Abstract

We consider polynomials that are orthogonal on $[-1,1]$ with respect to a modified Jacobi weight $(1-x)^{\alpha}(1+x)^{\beta}h(x)$, with $\alpha,\beta>-1$ and h real analytic and stricly positive on $[-1,1]$. We obtain full asymptotic expansions for the monic and orthonormal polynomials outside the interval $[-1,1]$, for the recurrence coefficients and for the leading coefficients of the orthonormal polynomials. We also deduce asymptotic behavior for the Hankel determinants and for the monic orthogonal polynomials on the interval $[-1,1]$. For the asymptotic analysis we use the steepest descent technique for Riemann–Hilbert problems developed by Deift and Zhou, and applied to orthogonal polynomials on the real line by Deift, Kriecherbauer, McLaughlin, Venakides, and Zhou. In the steepest descent method we will use the

Szegő function associated with the weight and for the local analysis around the endpoints ±1 we use Bessel functions of appropriate order, whereas Deift et al. use Airy functions.

1 Introduction and statement of results

1.1 Introduction

Strong asymptotics for the classical orthogonal polynomials (Hermite, Laguerre and Jacobi polynomials) are known from the book of Szegő [42, Section 8.21]. Szegő himself developed the asymptotic theory of orthogonal polynomials on the unit circle, and on the unit interval for weights that satisfy the Szegő condition, see [42] or [21]. During the last thirty years many asymptotic results were found for polynomials that are orthogonal with respect to various classes of weights, see the surveys [33, 34, 35, 39], and the monographs [31] and [44]. These developments were related to and partly motivated by questions from approximation theory, in particular Padé approximation and weighted polynomial approximation.

Recent developments in the theory of random matrices [36] provided a renewed interest in orthogonal polynomials from a different perspective. For example, when the size of the matrices tends to infinity, local statistical properties of the eigenvalues are related to the strong asymptotics of the associated orthogonal polynomials. Important new techniques for obtaining asymptotics for orthogonal polynomials in all regions of the complex plane were subsequently developed by Bleher and Its [8] and by Deift et al. [10, 11, 12, 24]. The asymptotic analysis in the latter papers is based on the characterization of the orthogonal polynomials by means of a Riemann–Hilbert problem for 2×2 matrix valued functions due to Fokas, Its, and Kitaev [20], together with an application of the steepest descent method of Deift and Zhou, introduced in [15] and further developed in [4, 14, 16] and the papers cited before. See [10, 13, 25] for an introduction, and [5, 9, 17, 18, 19, 23, 26, 27, 28, 29, 30, 37, 41, 45, 46] for the latest developments. A different method to obtain strong asymptotics for orthogonal polynomials was recently developed by Wong and co-authors, see e.g. [32, 40, 47].

The orthogonal polynomials considered in [11, 12] are orthogonal with respect to an exponential weight $e^{-Q(x)}$ on $\mathbb{R}$ or with respect to varying weights $e^{-nV(x)}$ on $\mathbb{R}$. Inspired by these papers, we consider here polynomials that are orthogonal on a finite interval $[-1, 1]$ with respect to a modified Jacobi weight

$$w(x) = (1-x)^{\alpha}(1+x)^{\beta}h(x), \qquad x \in [-1,1], \tag{1.1}$$

where $\alpha, \beta > -1$ and $h(x)$ is real analytic and strictly positive on $[-1, 1]$. The main difference between the weights (1.1) and the weights $e^{-Q(x)}$ and $e^{-nV(x)}$ where Q is a polynomial and V is real analytic on $\mathbb{R}$, lies in the behavior near the fixed endpoints ±1. In the language of random matrix theory, this is the difference between the hard edge and the soft edge of the spectrum [38, 43]. While the analysis near the soft edge of the spectrum typically involves Airy functions, near the hard edge we expect Bessel functions.

We use $\pi_n(x) = \pi_n(x; w)$ to denote the monic polynomial of degree n orthogonal with respect to the weight w on $[-1, 1]$. Thus

$$\int_{-1}^{1} \pi_n(x; w) x^k w(x)\, dx = 0, \qquad \text{for } k = 0, 1, \ldots, n-1,$$

and $p_n(x) = p_n(x; w)$ to denote the corresponding orthonormal polynomials. Thus

$$p_n(x) = \gamma_n \pi_n(x),$$

where $\gamma_n > 0$ is the leading coefficient of p_n.

The weights (1.1) belong to the class of weights that satisfy the Szegő condition

$$\int_{-1}^{1} \frac{\log w(x)}{\sqrt{1-x^2}} dx > -\infty. \tag{1.2}$$

Szegő's theory, see [21, 42], provides the strong asymptotics of the polynomials p_n and π_n and the leading coefficients γ_n as $n \to \infty$. To state the results, we need the function

$$\varphi(z) = z + (z^2-1)^{1/2}, \qquad z \in \mathbb{C} \setminus [-1,1], \tag{1.3}$$

which is the conformal map from $\mathbb{C} \setminus [-1,1]$ onto the exterior of the unit circle. In (1.3) we take that branch of $(z^2-1)^{1/2}$ which is analytic in $\mathbb{C} \setminus [-1,1]$ and behaves like z as $z \to \infty$. Similar conventions will be used later on. We also need the so-called Szegő function associated with a weight w satisfying (1.2), which for our purposes we define as the function $D(z) = D(z; w)$ given by

$$D(z) = \exp\left(\frac{(z^2-1)^{1/2}}{2\pi} \int_{-1}^{1} \frac{\log w(x)}{\sqrt{1-x^2}} \frac{dx}{z-x} \right), \qquad \text{for } z \in \mathbb{C} \setminus [-1,1]. \tag{1.4}$$

The function $D(z)$ is a non-zero analytic function on $\mathbb{C} \setminus [-1,1]$ such that

$$D_+(x) D_-(x) = w(x), \qquad \text{for a.e. } x \in (-1,1),$$

where $D_+(x)$ and $D_-(x)$ denote the limiting values of $D(z)$ as z approaches x from above and below, respectively. The limit at infinity

$$D_\infty = \lim_{z \to \infty} D(z) = \exp\left(\frac{1}{2\pi} \int_{-1}^{1} \frac{\log w(x)}{\sqrt{1-x^2}} dx \right)$$

exists and is a positive real number.

If the weight w on $[-1,1]$ satisfies the Szegő condition, then the following hold, see e.g. [42], [21]:

$$\lim_{n \to \infty} \frac{\gamma_n}{2^n} = \frac{1}{\sqrt{\pi} D_\infty} = \frac{1}{\sqrt{\pi}} \exp\left(-\frac{1}{2\pi} \int_{-1}^{1} \frac{\log w(x)}{\sqrt{1-x^2}} dx \right), \tag{1.5}$$

$$\lim_{n \to \infty} \frac{p_n(z)}{\varphi(z)^n} = \frac{\varphi(z)^{1/2}}{\sqrt{2\pi} (z^2-1)^{1/4} D(z)}, \tag{1.6}$$

and

$$\lim_{n \to \infty} \frac{2^n \pi_n(z)}{\varphi(z)^n} = \frac{D_\infty}{D(z)} \frac{\varphi(z)^{1/2}}{\sqrt{2} (z^2-1)^{1/4}}. \tag{1.7}$$

The limits (1.6) and (1.7) hold uniformly for z in compact subsets of $\mathbb{C} \setminus [-1,1]$.

Remark 1.1 Since the Szegő function of $\sqrt{1-x^2}$ is equal to $(z^2-1)^{1/4}\varphi(z)^{-1/2}$, we may also write (1.6) as

$$\lim_{n\to\infty} \frac{p_n(z)}{\varphi(z)^n} = \frac{1}{\sqrt{2\pi} D(z; \sqrt{1-x^2} w(x))}, \tag{1.8}$$

which is the form usually found in the literature, see e.g. [44, Lemma 1.8.]. Because of (1.8), $D(z; \sqrt{1-x^2}w(x))$ is sometimes called the Szegő function associated with w, instead of $D(z; w)$. We found it more convenient to use (1.6). This form was also used, for example, in [6, 7].

Remark 1.2 There are also results for the orthogonal polynomials on the interval $[-1, 1]$ under conditions that are somewhat stronger than the Szegő condition, see e.g. [21, 31, 42].

In this paper, we give more precise asymptotic results than (1.5), (1.6), (1.7) for the special weights (1.1). We are able to obtain full asymptotic expansions for γ_n, π_n, and p_n, as well as for the coefficients a_n and b_n in the three-term recurrence relation

$$\pi_{n+1}(z) = (z - b_n)\pi_n(z) - a_n^2 \pi_{n-1}(z), \tag{1.9}$$

satisfied by the monic orthogonal polynomials.

From our analysis we are also able to derive strong asymptotics for the orthogonal polynomials in the open interval $(-1, 1)$, as well as near the endpoints ± 1. In a follow-up paper [29] we discuss its consequences for the level spacings of eigenvalues in the unitary random matrix ensembles associated with the weights (1.1).

Besides the mapping function φ and the Szegő function D, the statement of the results involves certain coefficients that are determined by the extra factor h in the weight. Since h is real analytic and strictly positive on $[-1, 1]$, there is a neighborhood U of $[-1, 1]$ such that h has an analytic extension to U (also denoted by h) with positive real part. Then $\log h$ is defined and analytic on U, where we take the branch of the logarithm which is real on $[-1, 1]$. For definiteness, we take U of the form

$$U := \{z \in \mathbb{C} \mid d(z, [-1, 1]) < r\} \tag{1.10}$$

for some $0 < r < 1$, where $d(z, [-1, 1])$ denotes the distance from z to $[-1, 1]$.

Definition 1.3 Let γ be a closed contour in $U \setminus [-1, 1]$, encircling the interval $[-1, 1]$ once in the positive direction. We define two sequences (c_n) and (d_n) of coefficients by

$$c_n = \frac{1}{2\pi i} \int_\gamma \frac{\log h(\zeta)}{(\zeta^2-1)^{1/2}} \frac{d\zeta}{(\zeta-1)^{n+1}}, \tag{1.11}$$

and

$$d_n = \frac{1}{2\pi i} \int_\gamma \frac{\log h(\zeta)}{(\zeta^2-1)^{1/2}} \frac{d\zeta}{(\zeta+1)^{n+1}}, \tag{1.12}$$

for $n = 0, 1, 2, \ldots$.

Note that c_n and d_n do not depend on the precise form of the contour γ.

1.2 Asymptotics for monic polynomials

Our first result concerns the monic orthogonal polynomials π_n. It is similar to Theorem 8.21.9 of [42] where a full asymptotic expansion for the usual Jacobi polynomials $P_n^{(\alpha,\beta)}(z)$ (that is, $h \equiv 1$) was found.

Theorem 1.4 *For $z \in \mathbb{C} \setminus [-1,1]$, we have that $2^n \pi_n(z) \varphi(z)^{-n}$ has an asymptotic expansion in powers of $1/n$ of the form*

$$\frac{2^n \pi_n(z)}{\varphi(z)^n} \sim \frac{D_\infty}{D(z)} \frac{\varphi(z)^{1/2}}{\sqrt{2}(z^2-1)^{1/4}} \left[1 + \sum_{k=1}^{\infty} \frac{\Pi_k(z)}{n^k}\right], \qquad \textit{as } n \to \infty.$$

This expansion is valid uniformly on compact subsets of $\overline{\mathbb{C}} \setminus [-1,1]$. The functions $\Pi_k(z)$ are analytic on $\mathbb{C} \setminus [-1,1]$, and are explicitly computable. The first two are

$$\Pi_1(z) = -\frac{4\alpha^2-1}{8(\varphi(z)-1)} + \frac{4\beta^2-1}{8(\varphi(z)+1)}, \tag{1.13}$$

$$\begin{aligned}\Pi_2(z) = {} & \frac{(4\alpha^2-1)(\alpha+\beta+c_0)}{16(\varphi(z)-1)} - \frac{(4\beta^2-1)(\alpha+\beta+d_0)}{16(\varphi(z)+1)} - \frac{(4\alpha^2-1)(4\beta^2-1)}{128(z^2-1)} \\ & + \frac{2\alpha^2+2\beta^2-5}{64}\left[\frac{4\alpha^2-1}{(\varphi(z)-1)^2} + \frac{4\beta^2-1}{(\varphi(z)+1)^2}\right].\end{aligned} \tag{1.14}$$

Remark 1.5 The functions $\Pi_k(z)$ are all rational function in $\varphi(z)$, that vanish at ∞. With increasing k, the functions $\Pi_k(z)$ are increasingly more complicated.

If $4\alpha^2 - 1 = 4\beta^2 - 1 = 0$, then it turns out that all functions $\Pi_k(z)$ are identically zero. In that case one can in fact prove that

$$\frac{2^n \pi_n(z)}{\varphi(z)^n} = \frac{D_\infty}{D(z)} \frac{\varphi(z)^{1/2}}{\sqrt{2}(z^2-1)^{1/4}} \left[1 + O\left(e^{-cn}\right)\right], \qquad \text{as } n \to \infty$$

for some $c > 0$, cf. [25].

1.3 Asymptotics for leading coefficients

The leading coefficients γ_n of the orthonormal polynomials p_n also have an asymptotic expansion in powers of $1/n$:

Theorem 1.6 *We have the following asymptotic expansion for $2^{-n}\gamma_n$*

$$\frac{\gamma_n}{2^n} \sim \frac{1}{\sqrt{\pi} D_\infty}\left[1 + \sum_{k=1}^{\infty} \frac{\Gamma_k}{n^k}\right], \qquad \textit{as } n \to \infty, \tag{1.15}$$

where the coefficients Γ_k are explicitly computable. The first two are

$$\Gamma_1 = -\frac{4\alpha^2-1}{16} - \frac{4\beta^2-1}{16}, \tag{1.16}$$

$$\begin{aligned}\Gamma_2 = {} & \frac{4\alpha^2-1}{32}(\alpha+\beta+c_0) + \frac{4\beta^2-1}{32}(\alpha+\beta+d_0) \\ & + \left(2\alpha^2+2\beta^2+7\right)\left[\frac{4\alpha^2-1}{256} + \frac{4\beta^2-1}{256}\right].\end{aligned} \tag{1.17}$$

The coefficients Γ_k are polynomial expressions in α, β, and the coefficients c_n and d_n, defined in (1.11) and (1.12). It turns out that Γ_{2k} and Γ_{2k+1} depend only on

$$\alpha, \beta, c_0, d_0, \ldots, c_{k-1}, d_{k-1}.$$

1.4 Asymptotics for orthonormal polynomials

Since $p_n = \gamma_n \pi_n$, we obtain from Theorem 1.6 and Theorem 1.4:

Corollary 1.7 *For $z \in \mathbb{C}\setminus[-1,1]$, we have that $p_n(z)\varphi(z)^{-n}$ has an asymptotic expansion in powers of $1/n$ of the form*

$$\frac{p_n(z)}{\varphi(z)^n} \sim \frac{\varphi(z)^{1/2}}{\sqrt{2\pi}(z^2-1)^{1/4}D(z)}\left[1+\sum_{k=1}^{\infty}\frac{P_k(z)}{n^k}\right], \qquad \text{as } n\to\infty.$$

The expansion is valid uniformly on compact subsets of $\overline{\mathbb{C}}\setminus[-1,1]$. The functions $P_k(z)$ are analytic on $\mathbb{C}\setminus[-1,1]$, and are explicitly computable. The first two are

$$P_1(z) = -\frac{4\alpha^2-1}{16}\frac{\varphi(z)+1}{\varphi(z)-1} - \frac{4\beta^2-1}{16}\frac{\varphi(z)-1}{\varphi(z)+1},$$

$$\begin{aligned} P_2(z) \;=\; & \frac{(4\alpha^2-1)(\alpha+\beta+c_0)}{32}\frac{\varphi(z)+1}{\varphi(z)-1} + \frac{(4\beta^2-1)(\alpha+\beta+d_0)}{32}\frac{\varphi(z)-1}{\varphi(z)+1} \\ & + \frac{(4\alpha^2-1)^2}{128(\varphi(z)-1)} + \frac{(4\beta^2-1)^2}{128(\varphi(z)+1)} - \frac{(4\alpha^2-1)(4\beta^2-1)}{64}\frac{\varphi^2(z)+1}{(\varphi^2(z)-1)^2} \\ & + (2\alpha^2+2\beta^2-5)\left[\frac{4\alpha^2-1}{64\,(\varphi(z)-1)^2} + \frac{4\beta^2-1}{64\,(\varphi(z)+1)^2}\right] \\ & + (2\alpha^2+2\beta^2+7)\left[\frac{4\alpha^2-1}{256} + \frac{4\beta^2-1}{256}\right]. \end{aligned}$$

1.5 Asymptotics for Hankel determinants

The Hankel determinant D_n associated with w is

$$D_n = \det\left(\int_{-1}^{1} x^{j+k} w(x)dx\right)_{j,k=0,\ldots,n}, \tag{1.18}$$

see [42, Chapter II]. Since $\gamma_n = \sqrt{\frac{D_{n-1}}{D_n}}$ [42, Section 2.2], we have that

$$\frac{D_n}{D_0} = \prod_{j=1}^{n} \gamma_j^{-2}. \tag{1.19}$$

From Theorem 1.6 we then obtain the following asymptotic formula for D_n as $n\to\infty$.

Corollary 1.8 *There is a constant $C > 0$ such that*

$$D_n = C \left(\frac{1}{2}\right)^{n^2} \left(\frac{\pi D_\infty^2}{2}\right)^n n^{\frac{4\alpha^2-1}{8}+\frac{4\beta^2-1}{8}} \left(1 + O\left(\frac{1}{n}\right)\right) \tag{1.20}$$

as $n \to \infty$.

Proof. Re-write (1.19) as

$$\frac{D_n}{D_0} = \prod_{j=1}^{n} \left(\frac{2^j}{\sqrt{\pi} D_\infty}\right)^{-2} \times \prod_{j=1}^{n} \left(1 + \frac{\Gamma_1}{j}\right)^{-2} \times \prod_{j=1}^{n} \left(\frac{\sqrt{\pi} D_\infty}{2^j} \frac{\gamma_j}{1 + \frac{\Gamma_1}{j}}\right)^{-2} \tag{1.21}$$

The first two factors are explicit. The first one is equal to

$$\left(\frac{1}{2}\right)^{n^2} \left(\frac{\pi D_\infty^2}{2}\right)^n \tag{1.22}$$

and the second one is equal to

$$C_1 n^{-2\Gamma_1} \left(1 + O\left(\frac{1}{n}\right)\right). \tag{1.23}$$

The third factor is the partial product of a convergent infinite product, since by (1.15) we have

$$\frac{\sqrt{\pi} D_\infty}{2^j} \frac{\gamma_j}{1 + \frac{\Gamma_1}{j}} = \frac{1 + \frac{\Gamma_1}{j} + O(\frac{1}{j^2})}{1 + \frac{\Gamma_1}{j}} = 1 + O\left(\frac{1}{j^2}\right) \qquad \text{as } j \to \infty.$$

If C_2 is the value of the infinite product, then the third factor in (1.21) is

$$C_2 \prod_{j=n+1}^{\infty} \left(\frac{\sqrt{\pi} D_\infty}{2^j} \frac{\gamma_j}{1 + \frac{\Gamma_1}{j}}\right)^2 = C_2 \left(1 + O\left(\frac{1}{n}\right)\right). \tag{1.24}$$

Inserting (1.22), (1.23), and (1.24) into (1.21), and using (1.16), we obtain (1.20) with constant $C = C_1 C_2 D(0)$. □

Remark 1.9 The $O(1/n)$ term in (1.23) and (1.24) can be expanded into a complete asymptotic expansion, with explicitly computable constants depending only on the coefficients Γ_j in the expansion of γ_n. On the other hand, we cannot evaluate explicitly the constant C with our methods. For the determination of C in certain cases, see [22] and the references cited therein. This is known as Szegő's strong limit for Hankel determinants.

1.6 Asymptotics for recurrence coefficients

The monic orthogonal polynomials satisfy a three term recurrence relation of the form

$$\pi_{n+1}(z) = (z - b_n)\pi_n(z) - a_n^2 \pi_{n-1}(z).$$

In our next result we give an asymptotic expansion of these recurrence coefficients.

Theorem 1.10 *We have the following asymptotic expansion for* a_n *and* b_n

$$a_n \sim \frac{1}{2} + \sum_{k=2}^{\infty} \frac{A_k}{n^k}\ , \qquad \text{as } n \to \infty, \tag{1.25}$$

$$b_n \sim \sum_{k=2}^{\infty} \frac{B_k}{n^k}\ , \qquad \text{as } n \to \infty. \tag{1.26}$$

The coefficients A_k *and* B_k *are explicitly computable. The first few are*

$$A_2 = -\frac{4\alpha^2-1}{32} - \frac{4\beta^2-1}{32}, \tag{1.27}$$

$$A_3 = \frac{4\alpha^2-1}{32}\,(\alpha+\beta+c_0) + \frac{4\beta^2-1}{32}\,(\alpha+\beta+d_0), \tag{1.28}$$

$$\begin{aligned} A_4 = &-(3\alpha^2+3\beta^2+6\alpha\beta+1)\left[\frac{4\alpha^2-1}{128}+\frac{4\beta^2-1}{128}\right] - \frac{(4\alpha^2-1)(4\beta^2-1)}{256} \\ &- \frac{4\alpha^2-1}{128}\,3c_0(2\alpha+2\beta+c_0) - \frac{4\beta^2-1}{128}\,3d_0(2\alpha+2\beta+d_0), \end{aligned} \tag{1.29}$$

and

$$B_2 = \frac{\beta^2-\alpha^2}{4}, \tag{1.30}$$

$$B_3 = -\frac{\beta^2-\alpha^2}{4}\,(1+\alpha+\beta) + c_0\,\frac{4\alpha^2-1}{16} - d_0\,\frac{4\beta^2-1}{16}, \tag{1.31}$$

$$\begin{aligned} B_4 = &-\frac{4\alpha^2-1}{64}\,3c_0(2\alpha+2\beta+2+c_0) + \frac{4\beta^2-1}{64}\,3d_0(2\alpha+2\beta+2+d_0) \\ &+ \frac{\beta^2-\alpha^2}{16}\left(6\alpha+6\beta+3\alpha^2+3\beta^2+6\alpha\beta+4\right). \end{aligned} \tag{1.32}$$

Remark 1.11 Note that $A_1 = B_1 = 0$. The coefficients A_2 and B_2 only depend on α and β. This means that up to order $1/n^2$ the recurrence coefficients agree with the recurrence coefficients of the pure Jacobi weight $(1-x)^\alpha(1+x)^\beta$ as $n \to \infty$. The effect of the extra factor h in w starts playing a role in the $1/n^3$-term by means of the coefficients c_0 and d_0.

It turns out that for the case $4\alpha^2-1 = 4\beta^2-1 = 0$, all coefficients A_k and B_k vanish. In that case one can prove that $a_n = \frac{1}{2} + O(e^{-cn})$ and $b_n = O(e^{-cn})$ for some $c > 0$, cf. [25].

1.7 Asymptotics for monic polynomials on $[-1,1]$

Our final results concern strong asymptotics for π_n on the interval of orthogonality $[-1,1]$. The asymptotic behavior of π_n in $(-1,1)$ is given by the following theorem.

Theorem 1.12 *For $x \in (-1,1)$*

$$\pi_n(x) = \frac{\sqrt{2}D_\infty}{2^n\sqrt{w(x)}(1-x^2)^{1/4}}$$
$$\times \left[\Big(1+O(1/n)\Big)\cos\Big((n+1/2)\arccos x + \psi(x) - \frac{\pi}{4}\Big)\right.$$
$$\left. + O(1/n)\cos\Big((n-1/2)\arccos x + \psi(x) - \frac{\pi}{4}\Big)\right], \tag{1.33}$$

as $n \to \infty$. The error terms hold uniformly for x in compact subsets of $(-1,1)$ and have a full asymptotic expansion in terms of $1/n$, which can be calculated explicitly. In (1.33) the phase function ψ is given by

$$\psi(x) = \frac{1}{2}\Big(\alpha(\arccos x - \pi) + \beta \arccos x\Big) + \frac{\sqrt{1-x^2}}{2\pi} \fint_{-1}^{1} \frac{\log h(t)}{\sqrt{1-t^2}} \frac{dt}{t-x}. \tag{1.34}$$

The singular integral being understood in the sense of the principal value.

The asymptotic behavior of π_n near the endpoint 1 is given by the following theorem.

Theorem 1.13 *There exists $\delta > 0$ so that for $x \in (1-\delta, 1)$*

$$\pi_n(x) = \frac{\sqrt{\pi}D_\infty}{2^n\sqrt{w(x)}} \frac{(n\arccos x)^{1/2}}{(1-x^2)^{1/4}}$$
$$\times \left[\Big(1+O(1/n)\Big)\Big(\cos\zeta_1(x) J_\alpha(n\arccos x) + \sin\zeta_1(x) J_\alpha'(n\arccos x)\Big)\right.$$
$$\left. + O(1/n)\Big(\cos\zeta_2(x) J_\alpha(n\arccos x) + \sin\zeta_2(x) J_\alpha'(n\arccos x)\Big)\right], \tag{1.35}$$

as $n \to \infty$. The error terms hold uniformly for $x \in (1-\delta, 1)$ and have a full asymptotic expansion in powers of $1/n$, which can be calculated explicitly. In (1.35), J_α is the usual Bessel function of order α, and

$$\zeta_{1,2}(x) = \pm\frac{1}{2}\arccos x + \psi(x) + \frac{\alpha\pi}{2}, \tag{1.36}$$

where the $+$ holds for ζ_1, the $-$ for ζ_2, and where ψ is given by (1.34).

Near the endpoint -1, we can obtain similar asymptotic behavior in terms of Bessel functions of order β.

Remark 1.14 If $\alpha = \pm 1/2$, it turns out, after an easy calculation using the facts

$$J_{1/2}(z) = \sqrt{\frac{2}{\pi z}}\sin z, \qquad J_{-1/2}(z) = \sqrt{\frac{2}{\pi z}}\cos z,$$

that the asymptotic formula (1.35) is the same as formula (1.33), so that (1.33) holds uniformly in $[-1,1]$ for these cases. This can be explained from the fact that for these special choices of α we do not need to construct a parametrix near the endpoint 1, see [25].

Remark 1.15 The strong asymptotics (1.35) allow us to determine the asymptotics for the largest zeros of π_n. Let $1 > x_{n,1} > x_{n,2} > \cdots$ denote the zeros of π_n numbered in decreasing order, and let $0 < j_{\alpha,1} < j_{\alpha,2} < \cdots$ denote the positive zeros of the Bessel function J_α numbered in increasing order. Then, from (1.35) and Hurwitz' theorem we can deduce that, for every $k = 1, 2, \ldots$

$$x_{n,k} = 1 - \frac{j_{\alpha,k}^2}{2n^2} + O(1/n^3), \qquad \text{as } n \to \infty. \tag{1.37}$$

This agrees with the well-known asymptotics for the largest zeros of Jacobi polynomials, see e.g. [2, Section 22.16] or [42, Section 8.1].

Remark 1.16 The strong asymptotic formula (1.35) is also related to the behavior of spacings of eigenvalues near 1 (the hard edge) of random matrices from the associated unitary ensemble, see [29], where it was rigorously shown that the eigenvalue correlations can be expressed in terms of the Bessel kernel

$$\mathbb{J}_\alpha(x,y) = \frac{J_\alpha(\sqrt{x})\sqrt{y}J'_\alpha(\sqrt{v}) - J_\alpha(\sqrt{y})\sqrt{x}J'_\alpha(\sqrt{x})}{2(x-y)}.$$

1.8 Overview of the rest of the paper

As indicated in the beginning of the paper, our inspiration for this work comes from the papers [11, 12] by Deift, Kriecherbauer, McLaughlin, Venakides and Zhou. As in these papers, we use the Riemann–Hilbert approach to orthogonal polynomials, introduced by Fokas, Its and Kitaev [20], together with the steepest descent method for Riemann–Hilbert problems of Deift and Zhou [15].

In this method a number of transformations $Y \mapsto T \mapsto S \mapsto R$ are applied to the original Riemann–Hilbert problem in order to arrive at a Riemann-Hilbert problem for R, which is normalized at infinity, and whose jump matrices are uniformly close to the identity matrix. Then R is uniformly close to the identity matrix, which gives the leading terms in the asymptotic expansion for Y, and hence for the orthogonal polynomials. Using the fact that the jump matrices in the Riemann–Hilbert problem for R have a full asymptotic expansion in powers of $1/n$, we arrive at a full asymptotic expansion for R. Tracing back the steps $Y \mapsto T \mapsto S \mapsto R$, we obtain the full asymptotic expansions for the orthogonal polynomials and related quantities given in Theorems 1.4, 1.6, 1.10, 1.12, amd 1.13

All steps are analogous to the corresponding steps in [12]. The differences with [12] are connected with the endpoints ±1. The main differences are:

- In the setup of the Riemann–Hilbert problem for Y we have to be careful with the endpoints ±1. If $\alpha < 0$ or $\beta < 0$, then the weight is unbounded at 1 or -1, and the Riemann–Hilbert problem cannot be stated in terms of continuous boundary values. We include a growth condition in the Riemann–Hilbert problem in order to control the possible growth of Y near the endpoints in these cases, see (2.3)–(2.4).

- The first transformation $Y \mapsto T$ uses the conformal mapping φ from $\mathbb{C} \setminus [-1, 1]$ onto the exterior of the unit circle. This step is simpler than the corresponding step in [12], since there the transformation is based on the construction of a g-function, which depends on the weight and the degree n. There is also a preliminary step

$Y \mapsto U$ which scales the problem considered in [12], and which does not play a role here.

- The second transformation $T \mapsto S$ involves a factorization of the jump matrix and a contour deformation. The factorization is somewhat different from the one in [12]. After contour deformation it leads to jump matrices for S with w^{-1} in some of the entries. These jump matrices therefore have a non-integrable singularity in case $\alpha \geq 1$ or $\beta \geq 1$. Consequently, the Riemann–Hilbert problem for S cannot be stated in L^p-sense for some $p > 1$. Fortunately, the growth conditions at the endpoints still guarantee a unique solution, as we show.

- Before we can do the third transformation $S \mapsto R$ we have to construct a parametrix for S. The parametrix away from the endpoints depends in our case on the weight w. This is where the Szegő function for w comes in. In [12] this particular step did not depend on w.

- The construction of the parametrix near the endpoints ±1 involves (modified) Bessel functions (as expected), while in [12] it involves Airy functions. The construction is similar. One extra complication is that we have to take into account the growth condition at ±1.

- Having the parametrix for S in all regions, we can do the third transformation $S \mapsto R$ in the same way as in [12]. The asymptotic expansion of R follows from the known asymptotics of the modified Bessel functions at infinity, while of course it was based on the asymptotics of the Airy functions in [12].

Throughout the paper, w will be the weight (1.1) on $[-1, 1]$ with $\alpha, \beta > -1$. The function h is positive on $[-1, 1]$, and analytic with positive real part in the domain

$$U = \{z \in [-1, 1] \mid d(z, [-1, 1]) < r\}$$

with $0 < r < 1$.

The function φ is the conformal map (1.3), $D(z)$ is the Szegő function (1.4) associated with w, and D_∞ is the limit of $D(z)$ for $z \to \infty$. Other notation will be introduced when needed.

2 Riemann-Hilbert Problem

The Riemann–Hilbert approach starts from a characterization of the monic orthogonal polynomial π_n with respect to a weight w on $[-1, 1]$ through the following Riemann–Hilbert problem (RHP) for a 2×2 matrix valued function $Y(z)$.

RHP for Y:

(a) $Y(z)$ is analytic for $z \in \mathbb{C} \setminus [-1, 1]$.

(b) Y possesses continuous boundary values for $x \in (-1, 1)$ denoted by $Y_+(x)$ and $Y_-(x)$, where $Y_+(x)$ and $Y_-(x)$ denote the limiting values of $Y(z')$ as z' approaches x from above and below, respectively, and

$$Y_+(x) = Y_-(x) \begin{pmatrix} 1 & w(x) \\ 0 & 1 \end{pmatrix}, \qquad \text{for } x \in (-1, 1). \tag{2.1}$$

(c) $Y(z)$ has the following asymptotic behavior at infinity:

$$Y(z) = \left(I + O\left(\frac{1}{z}\right)\right)\begin{pmatrix} z^n & 0 \\ 0 & z^{-n} \end{pmatrix}, \qquad \text{as } z \to \infty. \tag{2.2}$$

(d) $Y(z)$ has the following behavior near $z = 1$:

$$Y(z) = \begin{cases} O\begin{pmatrix} 1 & |z-1|^{\alpha} \\ 1 & |z-1|^{\alpha} \end{pmatrix}, & \text{if } \alpha < 0, \\ O\begin{pmatrix} 1 & \log|z-1| \\ 1 & \log|z-1| \end{pmatrix}, & \text{if } \alpha = 0, \\ O\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}, & \text{if } \alpha > 0, \end{cases} \tag{2.3}$$

as $z \to 1$, $z \in \mathbb{C} \setminus [-1, 1]$.

(e) $Y(z)$ has the following behavior near $z = -1$:

$$Y(z) = \begin{cases} O\begin{pmatrix} 1 & |z+1|^{\beta} \\ 1 & |z+1|^{\beta} \end{pmatrix}, & \text{if } \beta < 0, \\ O\begin{pmatrix} 1 & \log|z+1| \\ 1 & \log|z+1| \end{pmatrix}, & \text{if } \beta = 0, \\ O\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}, & \text{if } \beta > 0, \end{cases} \tag{2.4}$$

as $z \to -1$, $z \in \mathbb{C} \setminus [-1, 1]$.

Remark 2.1 The O-terms in (2.3) and (2.4) are to be taken entrywise. So for example $Y(z) = O\begin{pmatrix} 1 & |z-1|^{\alpha} \\ 1 & |z-1|^{\alpha} \end{pmatrix}$ means that $Y_{11}(z) = O(1)$, $Y_{12}(z) = O(|z-1|^{\alpha})$, etc.

Remark 2.2 The RHP for orthogonal polynomials is due to Fokas, Its, and Kitaev [20]. See Deift [10] for an excellent exposition. The above formulation of the RHP for weights on $[-1, 1]$ differs from the formulation in [10] in two respects.

- In [10] uniqueness of the solution of the RHP is formulated in the setting of L^2 boundary values. Here in (b) we assume continuous boundary values on the open interval $(-1, 1)$, and we assume a certain growth condition at the endpoints ± 1 in (d) and (e). If $\alpha > -\frac{1}{2}$ and $\beta > -\frac{1}{2}$, then these growth conditions ensure that the RHP can also be taken in L^2 sense. This is no longer true if $\alpha \leq -\frac{1}{2}$ or $\beta \leq -\frac{1}{2}$. We will give an independent proof of the uniqueness of the solution of the RHP for Y in the first lemma.

- The conditions (d) and (e) control the behavior at the endpoints ± 1. There is no such condition in the RHP for orthogonal polynomials on the full real line, which are the object of research in [10, 11, 12]. We note that in the following we will encounter even more singular behavior at the endpoints.

Lemma 2.3 *If a solution of the RHP for Y exists then it is unique.*

Proof. The proof is as in [10, p.44] except that we have to pay special attention to the behavior at the endpoints ±1.

Let Y be a solution. Then $\det Y$ is analytic on $\mathbb{C} \setminus [-1,1]$ and by the jump condition (2.1) we have for $x \in (-1,1)$,

$$(\det Y)_+(x) = \det\left(Y_+(x)\right) = \det\left(Y_-(x)\right) \det \begin{pmatrix} 1 & w(x) \\ 0 & 1 \end{pmatrix} = (\det Y)_-(x),$$

so that $\det Y$ is analytic in $\mathbb{C} \setminus \{-1,1\}$.

From (2.3) it follows that

$$\det Y(z) = \begin{cases} O\left(|z-1|^{\alpha}\right), & \text{if } \alpha < 0, \\ O\left(\log|z-1|\right), & \text{if } \alpha = 0, \\ O(1), & \text{if } \alpha > 0, \end{cases}$$

as $z \to 1$. Since $\alpha > -1$, the singularity of $\det Y$ at 1 is removable. Similarly it follows from (2.4) that the singularity at -1 is removable. Thus $\det Y$ is an entire function.

From (2.2) it follows that $\det Y(z) \to 1$, as $z \to \infty$. Therefore, by Liouville's theorem, we have $\det Y(z) = 1$ for every z. In particular, we see that $Y(z)$ is invertible for every z and $Y^{-1}(z)$ is analytic for $z \in \mathbb{C} \setminus [-1,1]$.

Now suppose that $\tilde{Y}$ is a second solution of the RHP for Y. Then $H(z) := \tilde{Y}(z)Y^{-1}(z)$ is defined and analytic for $z \in \mathbb{C} \setminus [-1,1]$. As in [10, p.44] we have that H is analytic across the interval $(-1,1)$. We have, since $\det Y = 1$,

$$\begin{aligned} H(z) &= \tilde{Y}(z)Y^{-1}(z) = \begin{pmatrix} \tilde{Y}_{11}(z) & \tilde{Y}_{12}(z) \\ \tilde{Y}_{21}(z) & \tilde{Y}_{22}(z) \end{pmatrix} \begin{pmatrix} Y_{22}(z) & -Y_{12}(z) \\ -Y_{21}(z) & Y_{11}(z) \end{pmatrix} \\ &= \begin{pmatrix} \tilde{Y}_{11}(z)Y_{22}(z) - \tilde{Y}_{12}(z)Y_{21}(z) & \tilde{Y}_{12}(z)Y_{11}(z) - \tilde{Y}_{11}(z)Y_{12}(z) \\ \tilde{Y}_{21}(z)Y_{22}(z) - \tilde{Y}_{22}(z)Y_{21}(z) & \tilde{Y}_{22}(z)Y_{11}(z) - \tilde{Y}_{21}(z)Y_{12}(z) \end{pmatrix}. \end{aligned}$$

Since Y and $\tilde{Y}$ both satisfy (2.3) it follows for each entry H_{ij} of H that

$$H_{ij}(z) = \begin{cases} O\left(|z-1|^{\alpha}\right), & \text{if } \alpha < 0, \\ O\left(\log|z-1|\right), & \text{if } \alpha = 0, \\ O(1), & \text{if } \alpha > 0, \end{cases}$$

as $z \to 1$. Thus the point 1 is a removable singularity for each H_{ij}. Similarly, the point -1 is a removable singularity for each H_{ij}. Therefore H is analytic in $\mathbb{C}$. Since $H(z) \to I$, as $z \to \infty$, it follows again by Liouville's theorem that $H = I$ and so $\tilde{Y} = Y$.

This proves the uniqueness of the solution of the RHP for Y. □

Theorem 2.4 *The matrix valued function $Y(z)$ given by*

$$Y(z) = \begin{pmatrix} \pi_n(z) & \frac{1}{2\pi i}\int_{-1}^{1} \frac{\pi_n(x)w(x)}{x-z}dx \\ -2\pi i \gamma_{n-1}^2 \pi_{n-1}(z) & -\gamma_{n-1}^2 \int_{-1}^{1} \frac{\pi_{n-1}(x)w(x)}{x-z}dx \end{pmatrix} \tag{2.5}$$

is the unique solution of the RHP for Y.

Recall that π_n is the monic polynomial of degree n orthogonal with respect to the weight w and that γ_n is the leading coefficient of the corresponding orthonormal polynomial.

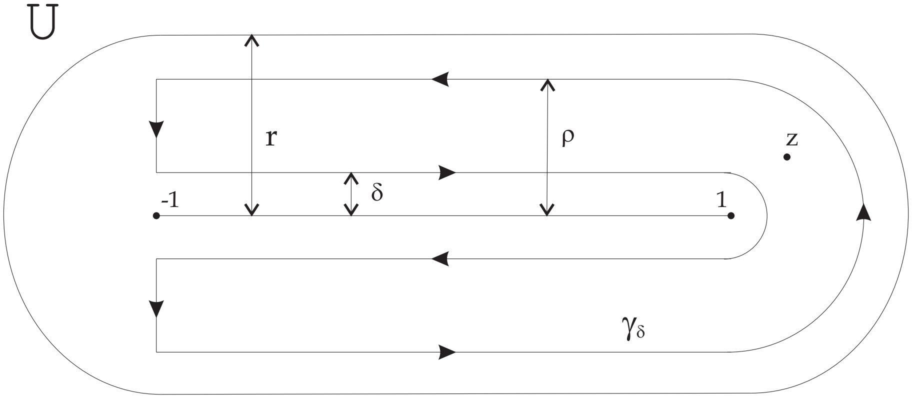

Figure 1: The contour γ_δ

Proof. It is obvious that $Y(z)$ is analytic for $z \in \mathbb{C} \setminus [-1,1]$. The proofs that Y satisfies (2.1) and (2.2) are as in [10]. We now concentrate on the proof of (2.3). It is clear that the $(1,1)$ and $(2,1)$ entries of Y are $O(1)$ as $z \to 1$. For the $(1,2)$ entry, we have to prove that for $z \to 1$,

$$Y_{12}(z) = \begin{cases} O\left(|z-1|^{\alpha}\right), & \text{if } \alpha < 0, \\ O(\log|z-1|), & \text{if } \alpha = 0, \\ O(1), & \text{if } \alpha > 0. \end{cases} \tag{2.6}$$

This is obvious if $\alpha > 0$, since then the limit

$$\lim_{z \to 1} Y_{12}(z) = \frac{1}{2\pi i} \int_{-1}^{1} \frac{\pi_n(x) w(x)}{x-1} dx \tag{2.7}$$

exists. Note that the integral in the right-hand side of (2.7) converges if $\alpha > 0$.

Consider the case $\alpha = 0$. Then

$$Y_{12}(z) = \frac{1}{2\pi i} \int_{-1}^{0} \frac{\pi_n(x)(1+x)^{\beta} h(x)}{x-z} dx + \frac{1}{2\pi i} \int_{0}^{1} \frac{\pi_n(x)(1+x)^{\beta} h(x)}{x-z} dx.$$

The first term is analytic in a neighborhood of 1. For the second term, we note that $\pi_n(x)(1+x)^{\beta}h(x)$ is analytic on $[0,1]$, hence it satisfies the Hölder condition on the interval $[0,1]$ so that by [1, p.521] we have

$$\frac{1}{2\pi i} \int_{0}^{1} \frac{\pi_n(x)(1+x)^{\beta} h(x)}{x-z} dx = c \log(z-1) + \Phi_0(z),$$

as $z \to 1$, $z \in \mathbb{C} \setminus [0,1]$, with some constant c and a bounded function $\Phi_0(z)$. Thus $Y_{12}(z) = O(\log|z-1|)$ as $z \to 1$, in case $\alpha = 0$.

Finally we consider the case $\alpha < 0$. Recall that the function h is analytic in the open neighborhood U of $[-1,1]$, see (1.10) and Figure 1. Choose $0 < \rho < r$, so that the disk with radius ρ and center 1 is contained in U. Let $|z-1| < \rho$ with $z \notin [-1,1]$. For $\delta > 0$ sufficiently small, z lies inside the closed contour γ_δ also shown in Figure 1. We define the function $\pi_n(\zeta)(\zeta-1)^{\alpha}(\zeta+1)^{\beta}h(\zeta)$ with a cut along $(-\infty, 1]$, so it is analytic in $U \setminus (-\infty, 1]$. Therefore, by Cauchy's theorem,

$$\frac{1}{2\pi i} \int_{\gamma_\delta} \frac{\pi_n(\zeta)(\zeta-1)^{\alpha}(\zeta+1)^{\beta} h(\zeta)}{\zeta - z} d\zeta = \pi_n(z)(z-1)^{\alpha}(z+1)^{\beta} h(z).$$

Letting $\delta \to 0$, we find after an easy calculation that

$$\Omega(z) + \frac{1}{2\pi i} \int_{-1}^{1} \frac{\pi_n(x) w(x)}{x - z} \left(e^{i\pi\alpha} - e^{-i\pi\alpha} \right) dx = \pi_n(z)(z-1)^\alpha (z+1)^\beta h(z),$$

with $\Omega(z)$ analytic for $|z-1| < \rho$. Therefore

$$Y_{12}(z) = \frac{\pi_n(z)(z+1)^\beta h(z)}{2i \sin \pi\alpha} (z-1)^\alpha - \frac{\Omega(z)}{2i \sin \pi\alpha}, \qquad \text{for } |z-1| < \rho,\ z \notin [-1,1].$$

Hence $Y_{12}(z) = O\left(|z-1|^\alpha\right)$ as $z \to 1$, in case $\alpha < 0$.

So (2.6) holds in all cases. Similarly it follows that $Y_{22}(z)$ has the correct order as $z \to 1$. Thus (2.3) holds. The proof that (2.4) holds follows in the same way. □

3 First transformation: $Y \mapsto T$

In this section we formulate an equivalent RHP. This new RHP is normalized at infinity, and its jump matrix has rapidly oscillating entries. Let σ_3 be the Pauli matrix

$$\sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$$

and define

$$T(z) = 2^{n\sigma_3} Y(z) \varphi(z)^{-n\sigma_3}, \qquad \text{for } z \in \mathbb{C} \setminus [-1,1], \tag{3.1}$$

with Y the unique solution of the RHP for Y, given by (2.5).

Recall that $\varphi(z) = z + (z^2-1)^{1/2}$ is the conformal map from $\mathbb{C} \setminus [-1,1]$ onto the exterior of the unit disk. So it is clear from (3.1) that T is analytic in $\mathbb{C} \setminus [-1,1]$.

We have for $x \in (-1,1)$,

$$\varphi_+(x)\varphi_-(x) = \left(x + i\sqrt{1-x^2}\right)\left(x - i\sqrt{1-x^2}\right) = 1, \tag{3.2}$$

and so, by (2.1) and (3.1), T satisfies the following jump relation on $(-1,1)$

$$\begin{aligned}
T_+(x) &= 2^{n\sigma_3} Y_+(x) \varphi_+(x)^{-n\sigma_3} \\
&= 2^{n\sigma_3} Y_-(x) \begin{pmatrix} 1 & w(x) \\ 0 & 1 \end{pmatrix} \varphi_+(x)^{-n\sigma_3} \\
&= T_-(x) \varphi_-(x)^{n\sigma_3} \begin{pmatrix} 1 & w(x) \\ 0 & 1 \end{pmatrix} \varphi_+(x)^{-n\sigma_3} \\
&= T_-(x) \begin{pmatrix} \varphi_+(x)^{-2n} & w(x) \\ 0 & \varphi_-(x)^{-2n} \end{pmatrix}, \qquad \text{for } x \in (-1,1).
\end{aligned}$$

Using (2.2), (3.1), and the fact that $\varphi(z) = 2z + O(1/z)$ as $z \to \infty$, we have $T(z) = I + O(1/z)$ as $z \to \infty$. Finally, φ is bounded and bounded away from 0 in a neighborhood of ± 1. Thus, T has the same behavior as Y around the points ± 1. So, we proved that T is the solution of the following RHP.

RHP for $\boldsymbol{T}$:

(a) $T(z)$ is analytic for $z \in \mathbb{C} \setminus [-1,1]$.

(b) $T(z)$ satisfies the following jump relation on $(-1,1)$:

$$T_+(x) = T_-(x) \begin{pmatrix} \varphi_+(x)^{-2n} & w(x) \\ 0 & \varphi_-(x)^{-2n} \end{pmatrix}, \qquad \text{for } x \in (-1,1). \tag{3.3}$$

(c) $T(z)$ has the following behavior at infinity:

$$T(z) = I + O\left(\frac{1}{z}\right), \qquad \text{as } z \to \infty. \tag{3.4}$$

(d) $T(z)$ has the following behavior as $z \to 1$:

$$T(z) = \begin{cases} O\begin{pmatrix} 1 & |z-1|^{\alpha} \\ 1 & |z-1|^{\alpha} \end{pmatrix}, & \text{if } \alpha < 0, \\ O\begin{pmatrix} 1 & \log|z-1| \\ 1 & \log|z-1| \end{pmatrix}, & \text{if } \alpha = 0, \\ O\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}, & \text{if } \alpha > 0. \end{cases} \tag{3.5}$$

(e) $T(z)$ has the following behavior as $z \to -1$:

$$T(z) = \begin{cases} O\begin{pmatrix} 1 & |z+1|^{\beta} \\ 1 & |z+1|^{\beta} \end{pmatrix}, & \text{if } \beta < 0, \\ O\begin{pmatrix} 1 & \log|z+1| \\ 1 & \log|z+1| \end{pmatrix}, & \text{if } \beta = 0, \\ O\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}, & \text{if } \beta > 0. \end{cases} \tag{3.6}$$

The RHPs for T and Y are equivalent, since if T is any solution of the RHP for T then it similarly follows that

$$Y(z) = 2^{-n\sigma_3} T(z) \varphi(z)^{n\sigma_3}, \tag{3.7}$$

solves the RHP for Y. Thus, by Lemma 2.3, the RHP for T has a unique solution.

Remark 3.1 Note that the transformation $Y \mapsto T$ has the same form (3.1) for every weight w. What we mean is that we use the same function φ for every w. This is in contrast to the case of varying weights on the real line [11, 12], where the first transformation is based on the construction of a so-called g-function, which is specific for the weight in question (it may even be n-dependent).

In our situation the g-function is

$$g(z) = \log \varphi(z) = \log(z + (z^2-1)^{1/2}),$$

which is defined and analytic on $\mathbb{C} \setminus (-\infty, 1]$.

Remark 3.2 Since $\varphi_+(x)$ and $\varphi_-(x)$ have absolute value 1 for $x \in (-1,1)$, we see in (3.3) that the diagonal entries in the jump matrix for T have absolute value 1, which are rapidly oscillating for large n.

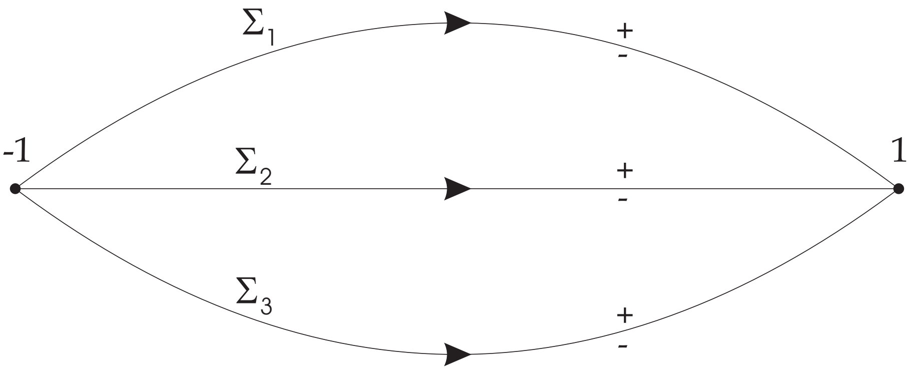

Figure 2: The lens Σ

4 Second transformation: $T \mapsto S$

The second transformation is based on a factorization of the jump matrix in (3.3) as a product of three matrices. A simple calculation, based on the fact that $\varphi_+(x)\varphi_-(x) = 1$ for $x \in (-1,1)$, shows that

$$\begin{pmatrix} \varphi_+(x)^{-2n} & w(x) \\ 0 & \varphi_-(x)^{-2n} \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ w(x)^{-1}\varphi_-(x)^{-2n} & 1 \end{pmatrix} \begin{pmatrix} 0 & w(x) \\ -w(x)^{-1} & 0 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ w(x)^{-1}\varphi_+(x)^{-2n} & 1 \end{pmatrix}. \tag{4.1}$$

As in [10, 11, 12] we deform the RHP for T into a RHP with jumps on a lens shaped contour $\Sigma = \Sigma_1 \cup \Sigma_2 \cup \Sigma_3$ as shown in Figure 2. Here Σ_1 and Σ_3 are the upper and lower lips of the lens, respectively, and $\Sigma_2 = [-1,1]$. The lens is contained in U. We also write

$$\Sigma_j^o = \Sigma_j \setminus \{-1,1\}, \qquad \text{for } j = 1,2,3.$$

The weight w has an analytic extension to $U \setminus ((-\infty,-1] \cup [1,\infty))$, also denoted by w, given by

$$w(z) = (1-z)^\alpha (1+z)^\beta h(z).$$

The extended weight is non-zero in $U \setminus ((-\infty,-1] \cup [1,\infty))$, since $\operatorname{Re} h > 0$ in U. Let T be the unique solution of the RHP for T and define the matrix valued function S on $\mathbb{C} \setminus \Sigma$ by

$$S(z) = \begin{cases} T(z), & \text{for } z \text{ outside the lens,} \\ T(z) \begin{pmatrix} 1 & 0 \\ -w(z)^{-1}\varphi(z)^{-2n} & 1 \end{pmatrix}, & \text{for } z \text{ in the upper part of the lens,} \\ T(z) \begin{pmatrix} 1 & 0 \\ w(z)^{-1}\varphi(z)^{-2n} & 1 \end{pmatrix}, & \text{for } z \text{ in the lower part of the lens.} \end{cases} \tag{4.2}$$

Straightforward calculations then show that S is a solution of the following RHP.

RHP for S:

(a) $S(z)$ is analytic for $z \in \mathbb{C} \setminus \Sigma$.

(b) $S(z)$ satisfies the following jump relations on $\Sigma \setminus \{-1, 1\}$:

$$S_+(z) = S_-(z) \begin{pmatrix} 1 & 0 \\ w(z)^{-1}\varphi(z)^{-2n} & 1 \end{pmatrix}, \qquad \text{for } z \in \Sigma_1^o \cup \Sigma_3^o, \tag{4.3}$$

$$S_+(x) = S_-(x) \begin{pmatrix} 0 & w(x) \\ -w(x)^{-1} & 0 \end{pmatrix}, \qquad \text{for } x \in (-1, 1). \tag{4.4}$$

(c) $S(z)$ has the following behavior as $z \to \infty$:

$$S(z) = I + O\left(\frac{1}{z}\right), \qquad \text{as } z \to \infty. \tag{4.5}$$

(d) For $\alpha < 0$, the matrix function $S(z)$ has the following behavior as $z \to 1$:

$$S(z) = O\begin{pmatrix} 1 & |z-1|^{\alpha} \\ 1 & |z-1|^{\alpha} \end{pmatrix}, \qquad \text{as } z \to 1, z \in \mathbb{C} \setminus \Sigma. \tag{4.6}$$

For $\alpha = 0$, $S(z)$ has the following behavior as $z \to 1$:

$$S(z) = O\begin{pmatrix} \log|z-1| & \log|z-1| \\ \log|z-1| & \log|z-1| \end{pmatrix}, \qquad \text{as } z \to 1, z \in \mathbb{C} \setminus \Sigma. \tag{4.7}$$

For $\alpha > 0$, $S(z)$ has the following behavior as $z \to 1$:

$$S(z) = \begin{cases} O\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}, & \text{as } z \to 1 \text{ outside the lens,} \\ O\begin{pmatrix} |z-1|^{-\alpha} & 1 \\ |z-1|^{-\alpha} & 1 \end{pmatrix}, & \text{as } z \to 1 \text{ inside the lens.} \end{cases} \tag{4.8}$$

(e) $S(z)$ has the same behavior near -1 if we replace in (4.6), (4.7), (4.8) α by β, $|z-1|$ by $|z+1|$ and take the limit $z \to -1$ instead of $z \to 1$.

It is not completely obvious that the RHPs for T and S are equivalent. We have that the (unique) solution of the RHP for T gives rise to a solution of the RHP for S by means of the formulas (4.2). Conversely, we may start from a solution $\tilde{S}$ of the RHP for S and define

$$\tilde{T}(z) = \begin{cases} \tilde{S}(z), & \text{for } z \text{ outside the lens,} \\ \tilde{S}(z) \begin{pmatrix} 1 & 0 \\ w(z)^{-1}\varphi(z)^{-2n} & 1 \end{pmatrix}, & \text{for } z \text{ in the upper part of the lens,} \\ \tilde{S}(z) \begin{pmatrix} 1 & 0 \\ -w(z)^{-1}\varphi(z)^{-2n} & 1 \end{pmatrix}, & \text{for } z \text{ in the lower part of the lens.} \end{cases} \tag{4.9}$$

We show that then $\tilde{T}$ is a solution of the RHP for T, which in turn implies, since the solution of the RHP for T is unique, that the solution of the RHP for S is unique as well.

Lemma 4.1 *Let $\tilde{S}$ be a solution of the RHP for S and define $\tilde{T}$ by the formulas* (4.9). *Then $\tilde{T}$ is a solution of the RHP for T.*

Proof. It is straightforward to show that $\tilde{T}$ satisfies parts (a), (b) and (c) of the RHP for T. We need to show that (d) and (e) also hold. Let T be the unique solution of the RHP for T. Then $H(z) := \tilde{T}(z)T^{-1}(z)$ is defined and analytic for $z \in \mathbb{C} \setminus [-1,1]$. Since $\tilde{T}$ and T have the same jumps on $(-1,1)$, it follows that H is analytic across $(-1,1)$. We have, since $\det T = 1$,

$$H(z) = \begin{pmatrix} \tilde{T}_{11}(z)T_{22}(z) - \tilde{T}_{12}(z)T_{21}(z) & \tilde{T}_{12}(z)T_{11}(z) - \tilde{T}_{11}(z)T_{12}(z) \\ \tilde{T}_{21}(z)T_{22}(z) - \tilde{T}_{22}(z)T_{21}(z) & \tilde{T}_{22}(z)T_{11}(z) - \tilde{T}_{21}(z)T_{12}(z) \end{pmatrix}. \tag{4.10}$$

From the definition (4.9) of $\tilde{T}(z)$ and (4.6)–(4.8) it follows that

$$\tilde{T}(z) = O\begin{pmatrix} 1 & |z-1|^{\alpha} \\ 1 & |z-1|^{\alpha} \end{pmatrix}, \qquad \text{as } z \to 1,$$

in case $\alpha < 0$, that

$$\tilde{T}(z) = O\begin{pmatrix} \log|z-1| & \log|z-1| \\ \log|z-1| & \log|z-1| \end{pmatrix}, \qquad \text{as } z \to 1,$$

in case $\alpha = 0$, and that

$$\tilde{T}(z) = \begin{cases} O\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}, & \text{as } z \to 1 \text{ outside the lens,} \\ O\begin{pmatrix} |z-1|^{-\alpha} & 1 \\ |z-1|^{-\alpha} & 1 \end{pmatrix}, & \text{as } z \to 1 \text{ inside the lens.} \end{cases}$$

in case $\alpha > 0$.

Combining this with (3.5) and (4.10), we obtain that

$$H(z) = O\begin{pmatrix} |z-1|^{\alpha} & |z-1|^{\alpha} \\ |z-1|^{\alpha} & |z-1|^{\alpha} \end{pmatrix}, \qquad \text{as } z \to 1, \tag{4.11}$$

in case $\alpha < 0$, that

$$H(z) = O\begin{pmatrix} \log|z-1| & (\log|z-1|)^2 \\ \log|z-1| & (\log|z-1|)^2 \end{pmatrix}, \qquad \text{as } z \to 1, \tag{4.12}$$

in case $\alpha = 0$, and that

$$H(z) = \begin{cases} O\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}, & \text{as } z \to 1 \text{ outside the lens,} \\ O\begin{pmatrix} |z-1|^{-\alpha} & |z-1|^{-\alpha} \\ |z-1|^{-\alpha} & |z-1|^{-\alpha} \end{pmatrix}, & \text{as } z \to 1 \text{ inside the lens,} \end{cases} \tag{4.13}$$

in case $\alpha > 0$.

In all cases it now follows that H has a removable singularity at 1. This is clear if $\alpha \leq 0$ from (4.11) and (4.12), since $\alpha > -1$. If $\alpha > 0$, then it follows from (4.13) that H remains bounded if we approach 1 from outside the lens. Then the entries of H

cannot have a pole at 1, since in the case of a pole, the function becomes unbounded if we approach 1 from all directions. Moreover, we also get from (4.13) that $(z-1)^m H(z)$ is bounded near 1, for any integer $m > \alpha$. Then the entries of H cannot have an essential singularity either, so that 1 is a removable singularity of H.

Similarly, it follows that in all cases, H has a removable singularity at -1. Therefore, H is entire. It follows from (3.4), (4.5), and (4.9) that $H(z) \to I$ as $z \to \infty$. So, by Liouville's theorem, $H(z) = I$. This gives $\tilde{T} = T$, so that indeed $\tilde{T}$ is the (unique) solution of the RHP for T. □

Remark 4.2 For $\alpha \geq 1$, the jump matrices (4.3) and (4.4) for S, as well as S itself, have a non-integrable singularity near $z = 1$, since the factor $w^{-1}(z)$ behaves like $(1-z)^{-\alpha}$ as $z \to 1$. It then follows that the RHP for S does not have a solution in any L^p sense with $p > 1$, if $\alpha \geq 1$.

Remark 4.3 Since $|\varphi(z)| > 1$ for every $z \in \mathbb{C} \setminus [-1, 1]$, we see from (4.3) that the jump matrix for S on $\Sigma_1^o \cup \Sigma_3^o$,

$$\begin{pmatrix} 1 & 0 \\ w(z)^{-1}\varphi(z)^{-2n} & 1 \end{pmatrix}$$

tends to the identity matrix as $n \to \infty$. So the effect of the transformation $T \mapsto S$ has been to transform the oscillating entries on the diagonal in the jump matrix for T into exponentially decaying off-diagonal entries in the jump matrix for S. This lies at the heart of the Deift–Zhou steepest descent method for Riemann–Hilbert problems.

5 The parametrix for the outside region

Since the jump matrix in (4.3) tends to the identity matrix as $n \to \infty$, we expect that the leading order asymptotics are determined by a solution N of the following RHP.

RHP for N:

(a) $N(z)$ is analytic for $z \in \mathbb{C} \setminus [-1, 1]$.

(b) $N(z)$ satisfies the following jump relation on the interval $(-1, 1)$:

$$N_+(x) = N_-(x) \begin{pmatrix} 0 & w(x) \\ -w(x)^{-1} & 0 \end{pmatrix}, \qquad \text{for } x \in (-1, 1). \tag{5.1}$$

(c) $N(z)$ has the following behavior as $z \to \infty$:

$$N(z) = I + O\left(\frac{1}{z}\right), \qquad \text{as } z \to \infty. \tag{5.2}$$

We present a solution of the RHP for N in terms of the Szegő function $D(z) = D(z; w)$ associated with w, see (1.4). The Szegő function is the scalar function $D : \mathbb{C} \setminus [-1, 1] \to \mathbb{C}$ that satisfies the following scalar RHP.

RHP for D:

(a) $D(z)$ has no zeros and is analytic for $z \in \mathbb{C} \setminus [-1,1]$.

(b) $D_+(x)D_-(x) = w(x)$ for $x \in (-1,1)$.

(c) $\lim_{z\to\infty} D(z) = D_\infty \in (0,\infty)$.

It is well-known and easy to check that D as given by (1.4) is indeed a solution of this RHP.

Remark 5.1 If D_1 and D_2 are the Szegő functions for the weights w_1 and w_2, respectively, then the product $D_1 D_2$ is the Szegő function for $w_1 w_2$. Since the Szegő function for the pure Jacobi weight $w_{\alpha,\beta}(x) = (1-x)^\alpha (1+x)^\beta$ is equal to

$$D(z; w_{\alpha,\beta}) = \frac{(z-1)^{\alpha/2}(z+1)^{\beta/2}}{\varphi(z)^{(\alpha+\beta)/2}}, \qquad \text{for } z \in \mathbb{C} \setminus [-1,1], \tag{5.3}$$

it follows that for $z \in \mathbb{C} \setminus [-1,1]$,

$$\begin{aligned} D(z;w) &= D(z; w_{\alpha,\beta}) D(z;h) \\ &= \frac{(z-1)^{\alpha/2}(z+1)^{\beta/2}}{\varphi(z)^{(\alpha+\beta)/2}} \exp\left(\frac{(z^2-1)^{1/2}}{2\pi} \int_{-1}^{1} \frac{\log h(x)}{\sqrt{1-x^2}} \frac{dx}{z-x} \right). \end{aligned} \tag{5.4}$$

Proposition 5.2 *A solution of the RHP for N is given by*

$$N(z) = D_\infty^{\sigma_3} \begin{pmatrix} \frac{a(z)+a(z)^{-1}}{2} & \frac{a(z)-a(z)^{-1}}{2i} \\ \frac{a(z)-a(z)^{-1}}{-2i} & \frac{a(z)+a(z)^{-1}}{2} \end{pmatrix} D(z)^{-\sigma_3}. \tag{5.5}$$

where $D(z) = D(z;w)$ is the Szegő function associated with w, and

$$a(z) = \frac{(z-1)^{1/4}}{(z+1)^{1/4}}. \tag{5.6}$$

Proof. If we seek a solution N of the RHP for N of the form

$$N(z) = D_\infty^{\sigma_3} N^{(1)}(z) D(z)^{-\sigma_3}, \tag{5.7}$$

then $N^{(1)}(z)$ is analytic in $\mathbb{C} \setminus [-1,1]$, and

$$N^{(1)}(z) = I + O\left(\frac{1}{z}\right), \qquad \text{as } z \to \infty.$$

Furthermore, using (5.1) and $D_+(x)D_-(x) = w(x)$ for $x \in (-1,1)$, we have

$$N_+^{(1)}(x) = N_-^{(1)}(x) \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \qquad \text{for } x \in (-1,1).$$

It is well-known (see [10, 11, 12]) that the RHP for $N^{(1)}$ is solved by

$$N^{(1)}(z) = \begin{pmatrix} 1 & 1 \\ i & -i \end{pmatrix} a(z)^{\sigma_3} \begin{pmatrix} 1 & 1 \\ i & -i \end{pmatrix}^{-1} = \begin{pmatrix} \frac{a(z)+a(z)^{-1}}{2} & \frac{a(z)-a(z)^{-1}}{2i} \\ \frac{a(z)-a(z)^{-1}}{-2i} & \frac{a(z)+a(z)^{-1}}{2} \end{pmatrix},$$

where $a(z)$ is given by (5.6). This proves (5.5). $\square$

6 Parametrix near the endpoints

The jump matrices for S and N are not uniformly close to each other near the endpoints ± 1. This is reflected in the fact that SN^{-1} is not bounded near the endpoints. We need a local analysis around these points. We consider the endpoint $z=1$ in detail, the analysis for $z=-1$ being similar. In a small but fixed neighborhood $U_\delta = \{z \mid |z-1| < \delta\}$ of $z=1$, with $0<\delta<r$ (so that the closure of U_δ lies in U) we construct a parametrix P, that satisfies exactly the same jump relations as S, that matches with N on the boundary ∂U_δ of U_δ, and that has the same behavior as $S(z)$ near $z=1$. We thus seek a matrix valued function P that satisfies the following RHP.

RHP for *P*:

(a) $P(z)$ is defined and analytic for $z \in U_{\delta_0} \setminus \Sigma$ for some $\delta_0 > \delta$.

(b) $P(z)$ satisfies the following jump relations on $U_\delta \cap \Sigma^o$:

$$P_+(z) = P_-(z) \begin{pmatrix} 1 & 0 \\ w(z)^{-1}\varphi(z)^{-2n} & 1 \end{pmatrix}, \qquad \text{for } z \in U_\delta \cap (\Sigma_1^o \cup \Sigma_3^o), \tag{6.1}$$

$$P_+(x) = P_-(x) \begin{pmatrix} 0 & w(x) \\ -w(x)^{-1} & 0 \end{pmatrix}, \qquad \text{for } x \in U_\delta \cap \Sigma_2^o. \tag{6.2}$$

(c) On ∂U_δ we have, as $n \to \infty$

$$P(z)N^{-1}(z) = I + O\left(\frac{1}{n}\right), \qquad \text{uniformly for } z \in \partial U_\delta \setminus \Sigma. \tag{6.3}$$

(d) For $\alpha < 0$, the matrix function $P(z)$ has the following behavior as $z \to 1$:

$$P(z) = O\begin{pmatrix} 1 & |z-1|^\alpha \\ 1 & |z-1|^\alpha \end{pmatrix}, \qquad \text{as } z \to 1, z \in U_\delta \setminus \Sigma. \tag{6.4}$$

For $\alpha = 0$, $P(z)$ has the following behavior as $z \to 1$:

$$P(z) = O\begin{pmatrix} \log|z-1| & \log|z-1| \\ \log|z-1| & \log|z-1| \end{pmatrix}, \qquad \text{as } z \to 1, z \in U_\delta \setminus \Sigma. \tag{6.5}$$

For $\alpha > 0$, $P(z)$ has the following behavior as $z \to 1$:

$$P(z) = \begin{cases} O\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}, & \text{as } z \to 1 \text{ outside the lens,} \\ O\begin{pmatrix} |z-1|^{-\alpha} & 1 \\ |z-1|^{-\alpha} & 1 \end{pmatrix}, & \text{as } z \to 1 \text{ inside the lens.} \end{cases} \tag{6.6}$$

To find P, we concentrate first on parts (a), (b), and (d). Later we will also consider the matching condition (6.3).

Recall that h is analytic with positive real part on U. Hence, the function

$$W(z) = \left((z-1)^\alpha (z+1)^\beta h(z)\right)^{1/2} \tag{6.7}$$

is defined and analytic for $z \in U \setminus (-\infty, 1]$. The branch of the square root is chosen which is positive for $z > 1$. Note that

$$W^2(z) = \begin{cases} e^{\alpha\pi i} w(z), & \text{for } \operatorname{Im} z > 0, \\ e^{-\alpha\pi i} w(z), & \text{for } \operatorname{Im} z < 0. \end{cases} \tag{6.8}$$

Thus in particular, $W_\pm^2(x) = e^{\pm\alpha\pi i} w(x)$ for $x \in (-1, 1)$, and so

$$W_+(x) W_-(x) = w(x), \qquad \text{for } x \in (-1, 1). \tag{6.9}$$

Thus W satisfies the same jump relation as the Szegő function $D(z)$. Note however that W does not extend to an analytic function on $\mathbb{C} \setminus [-1, 1]$.

We seek P in the form

$$P(z) = E_n(z) P^{(1)}(z) W(z)^{-\sigma_3} \varphi(z)^{-n\sigma_3}, \tag{6.10}$$

where the invertible matrix valued function E_n is analytic in a neighborhood of U_δ. By (6.1) and (6.10) the matrix function $P^{(1)}$ should satisfy on $U_\delta \cap (\Sigma_1^o \cup \Sigma_3^o)$ the jump relation

$$\begin{aligned} P_+^{(1)}(z) &= P_-^{(1)}(z) \varphi(z)^{-n\sigma_3} W(z)^{-\sigma_3} \begin{pmatrix} 1 & 0 \\ w(z)^{-1} \varphi(z)^{-2n} & 1 \end{pmatrix} W(z)^{\sigma_3} \varphi(z)^{n\sigma_3} \\ &= P_-^{(1)}(z) \begin{pmatrix} 1 & 0 \\ w(z)^{-1} W^2(z) & 1 \end{pmatrix} \\ &= P_-^{(1)}(z) \begin{pmatrix} 1 & 0 \\ e^{\pm\alpha\pi i} & 1 \end{pmatrix} \end{aligned}$$

where in the last step we used (6.8). In $e^{\pm\alpha\pi i}$ the $+$ holds on Σ_1^o and the $-$ on Σ_3^o. For $x \in (1 - \delta, 1)$, we find using (6.2), (6.9), (6.10), and the fact that $\varphi_+(x)\varphi_-(x) = 1$,

$$\begin{aligned} P_+^{(1)}(x) &= P_-^{(1)}(x) \varphi_-(x)^{-n\sigma_3} W_-(x)^{-\sigma_3} \begin{pmatrix} 0 & w(x) \\ -w(x)^{-1} & 0 \end{pmatrix} W_+(x)^{\sigma_3} \varphi_+(x)^{n\sigma_3} \\ &= P_-^{(1)}(x) \begin{pmatrix} 0 & w(x) W_-(x)^{-1} W_+(x)^{-1} \\ -w(x)^{-1} W_-(x) W_+(x) & 0 \end{pmatrix} \\ &= P_-^{(1)}(x) \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}. \end{aligned}$$

We therefore see that we must look for a matrix valued function $P^{(1)}$ that satisfies the following RHP.

RHP for $P^{(1)}$:

(a) $P^{(1)}(z)$ is defined and analytic for $z \in U_{\delta_0} \setminus \Sigma$ for some $\delta_0 > \delta$.

(b) $P^{(1)}(z)$ satisfies the following jump relations:

$$\begin{cases} P_+^{(1)}(z) = P_-^{(1)}(z) \begin{pmatrix} 1 & 0 \\ e^{\alpha\pi i} & 1 \end{pmatrix}, & \text{for } z \in U_\delta \cap \Sigma_1^o, \\ P_+^{(1)}(x) = P_-^{(1)}(x) \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, & \text{for } x \in U_\delta \cap \Sigma_2^o, \\ P_+^{(1)}(z) = P_-^{(1)}(z) \begin{pmatrix} 1 & 0 \\ e^{-\alpha\pi i} & 1 \end{pmatrix}, & \text{for } z \in U_\delta \cap \Sigma_3^o. \end{cases} \tag{6.11}$$

(c) For $\alpha < 0$, the matrix function $P^{(1)}(z)$ has the following behavior as $z \to 1$:

$$P^{(1)}(z) = O\begin{pmatrix} |z-1|^{\alpha/2} & |z-1|^{\alpha/2} \\ |z-1|^{\alpha/2} & |z-1|^{\alpha/2} \end{pmatrix}, \qquad \text{as } z \to 1, z \in U_\delta \setminus \Sigma.$$

For $\alpha = 0$, $P^{(1)}(z)$ has the following behavior as $z \to 1$:

$$P^{(1)}(z) = O\begin{pmatrix} \log|z-1| & \log|z-1| \\ \log|z-1| & \log|z-1| \end{pmatrix}, \qquad \text{as } z \to 1, z \in U_\delta \setminus \Sigma.$$

For $\alpha > 0$, $P^{(1)}(z)$ has the following behavior as $z \to 1$:

$$P^{(1)}(z) = \begin{cases} O\begin{pmatrix} |z-1|^{\alpha/2} & |z-1|^{-\alpha/2} \\ |z-1|^{\alpha/2} & |z-1|^{-\alpha/2} \end{pmatrix}, & \text{as } z \to 1 \text{ outside the lens,} \\ O\begin{pmatrix} |z-1|^{-\alpha/2} & |z-1|^{-\alpha/2} \\ |z-1|^{-\alpha/2} & |z-1|^{-\alpha/2} \end{pmatrix}, & \text{as } z \to 1 \text{ inside the lens.} \end{cases}$$

Remark 6.1 Note that the condition (c) in the RHP for $P^{(1)}$ follows from the condition (d) in the RHP for P, since

$$P^{(1)}(z) = E_n(z)^{-1}P(z)W(z)^{\sigma_3}\varphi(z)^{-n\sigma_3}$$

where φ is bounded and bounded away from 0 near $z = 1$, and $W(z)$ behaves like $c(z-1)^{\alpha/2}$, with a positive constant c, as $z \to 1$.

Remark 6.2 Observe that the jump matrices for $P^{(1)}$ in (6.11) are constants on the three parts Σ_1^o, Σ_2^o and Σ_3^o.

To construct $P^{(1)}$ we first define a function g as

$$g(z) = \log\varphi(z) = \log\left(z + (z^2-1)^{1/2}\right), \qquad \text{for } z \in \mathbb{C} \setminus (-\infty, 1]. \tag{6.12}$$

This function is analytic in $\mathbb{C}\setminus(-\infty,1]$ and for $x \in (-1,1)$ we have, since $\varphi_+(x)\varphi_-(x) = 1$, that $g_+(x) = -g_-(x)$. Therefore g^2 is also analytic across $(-1,1)$. Since $g^2(1) = 0$, the singularity at 1 is removable, so that the function f defined by

$$f(z) = g^2(z)/4, \qquad \text{for } z \in \mathbb{C} \setminus (-\infty, -1], \tag{6.13}$$

is analytic in $\mathbb{C} \setminus (-\infty, -1]$. The behavior of $g(z)$ near 1 is

$$g(z) = \sqrt{2}(z-1)^{1/2} - \frac{\sqrt{2}}{12}(z-1)^{3/2} + O\left((z-1)^{5/2}\right), \qquad \text{as } z \to 1, \tag{6.14}$$

and the behavior of $f(z)$ near 1 is

$$f(z) = \frac{1}{2}(z-1) - \frac{1}{12}(z-1)^2 + O\left((z-1)^3\right), \qquad \text{as } z \to 1. \tag{6.15}$$

Because f is analytic on $\mathbb{C}\setminus(-\infty,-1]$ and $f'(1) = 1/2 \neq 0$, f is a one-to-one conformal mapping on a neighborhood of 1. A more detailed analysis of f reveals that f is one-to-one on the disk $|z-1| < 2$ around 1. In any case, since $0 < \delta < r < 1$, we have that f is one-to-one on U_δ. Since $f(z)$ is real for z real, we then have that f maps $U_\delta \cap \mathbb{C}_\pm$ one-to-one onto $f(U_\delta) \cap \mathbb{C}_\pm$, where $\mathbb{C}_+ = \{z \mid \operatorname{Im} z > 0\}$ and $\mathbb{C}_- = \{z \mid \operatorname{Im} z < 0\}$.

We will use the mapping $\zeta = n^2 f(z)$ to transfer the RHP in the z-plane to a RHP in the ζ-plane. Consider the following RHP in the complex ζ-plane, on a contour Σ_Ψ consisting of three infinite rays,

$$\gamma_1 : \arg\zeta = 2\pi/3, \qquad \gamma_2 : \arg\zeta = \pi, \qquad \gamma_3 : \arg\zeta = -2\pi/3,$$

oriented as in Figure 3.

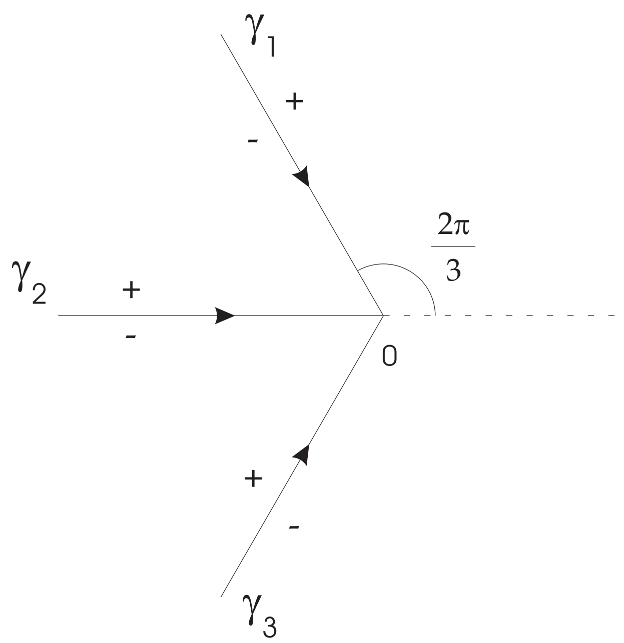

Figure 3: The contour Σ_Ψ

RHP for Ψ:

(a) $\Psi(\zeta)$ is analytic for $\zeta \in \mathbb{C} \setminus \Sigma_\Psi$,

(b) $\Psi(\zeta)$ satisfies the following jump relations:

$$\Psi_+(\zeta) = \Psi_-(\zeta) \begin{pmatrix} 1 & 0 \\ e^{\alpha\pi i} & 1 \end{pmatrix}, \qquad \text{for } \zeta \in \gamma_1, \tag{6.16}$$

$$\Psi_+(\zeta) = \Psi_-(\zeta) \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \qquad \text{for } \zeta \in \gamma_2, \tag{6.17}$$

$$\Psi_+(\zeta) = \Psi_-(\zeta) \begin{pmatrix} 1 & 0 \\ e^{-\alpha\pi i} & 1 \end{pmatrix}, \qquad \text{for } \zeta \in \gamma_3. \tag{6.18}$$

(c) For $\alpha < 0$, the matrix function $\Psi(\zeta)$ has the following behavior as $\zeta \to 0$:

$$\Psi(\zeta) = O\begin{pmatrix} |\zeta|^{\alpha/2} & |\zeta|^{\alpha/2} \\ |\zeta|^{\alpha/2} & |\zeta|^{\alpha/2} \end{pmatrix}, \qquad \text{as } \zeta \to 0. \tag{6.19}$$

For $\alpha = 0$, $\Psi(\zeta)$ has the following behavior as $\zeta \to 0$:

$$\Psi(\zeta) = O\begin{pmatrix} \log|\zeta| & \log|\zeta| \\ \log|\zeta| & \log|\zeta| \end{pmatrix}, \qquad \text{as } \zeta \to 0. \tag{6.20}$$

For $\alpha > 0$, $\Psi(\zeta)$ has the following behavior as $\zeta \to 0$:

$$\Psi(\zeta) = \begin{cases} O\begin{pmatrix} |\zeta|^{\alpha/2} & |\zeta|^{-\alpha/2} \\ |\zeta|^{\alpha/2} & |\zeta|^{-\alpha/2} \end{pmatrix}, & \text{as } \zeta \to 0 \text{ in } |\arg\zeta| < 2\pi/3, \\ O\begin{pmatrix} |\zeta|^{-\alpha/2} & |\zeta|^{-\alpha/2} \\ |\zeta|^{-\alpha/2} & |\zeta|^{-\alpha/2} \end{pmatrix}, & \text{as } \zeta \to 0 \text{ in } 2\pi/3 < |\arg\zeta| < \pi. \end{cases} \tag{6.21}$$

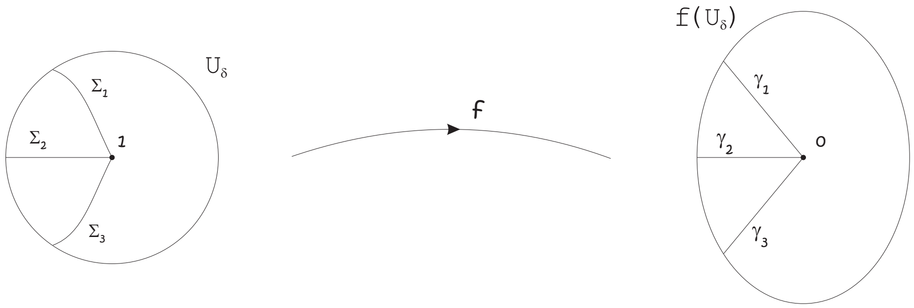

Figure 4: The definition of Σ_1, Σ_2 and Σ_3 in U_δ

In the above, we have chosen the angle $2\pi/3$ rather arbitrarily. It could be replaced by any angle in $(0, \pi)$. However, having chosen the angle, we *define* the contours $\Sigma_1 \cap U_\delta$ and $\Sigma_3 \cap U_\delta$ in U_δ as the preimages of the rays γ_1 and γ_3 under the mapping $\zeta = n^2 f(z)$, see Figure 4. Note that this definition does not depend on n. Then it follows immediately that if $\Psi(\zeta)$ is a solution of the RHP for Ψ we can define

$$P^{(1)}(z) = \Psi(n^2 f(z)), \tag{6.22}$$

and $P^{(1)}$ will satisfy the RHP for $P^{(1)}$.

We construct a solution Ψ out of (modified) Bessel functions of order α. We refer to Chapter 9 of [2] for definitions and properties of the modified Bessel functions I_α and K_α, and the Hankel functions $H_\alpha^{(1)}$ and $H_\alpha^{(2)}$, as well as their relation with the ordinary Bessel functions J_α and Y_α. We define $\Psi(\zeta)$ for $|\arg \zeta| < 2\pi/3$ as

$$\Psi(\zeta) = \begin{pmatrix} I_\alpha(2\zeta^{1/2}) & \frac{i}{\pi} K_\alpha(2\zeta^{1/2}) \\ 2\pi i \zeta^{1/2} I_\alpha'(2\zeta^{1/2}) & -2\zeta^{1/2} K_\alpha'(2\zeta^{1/2}) \end{pmatrix}. \tag{6.23}$$

For $2\pi/3 < \arg \zeta < \pi$ we define it as

$$\Psi(\zeta) = \begin{pmatrix} \frac{1}{2} H_\alpha^{(1)}(2(-\zeta)^{1/2}) & \frac{1}{2} H_\alpha^{(2)}(2(-\zeta)^{1/2}) \\ \pi \zeta^{1/2} \left(H_\alpha^{(1)}\right)'(2(-\zeta)^{1/2}) & \pi \zeta^{1/2} \left(H_\alpha^{(2)}\right)'(2(-\zeta)^{1/2}) \end{pmatrix} e^{\frac{1}{2}\alpha\pi i \sigma_3}. \tag{6.24}$$

And finally for $-\pi < \arg \zeta < -2\pi/3$ it is defined as

$$\Psi(\zeta) = \begin{pmatrix} \frac{1}{2} H_\alpha^{(2)}(2(-\zeta)^{1/2}) & -\frac{1}{2} H_\alpha^{(1)}(2(-\zeta)^{1/2}) \\ -\pi \zeta^{1/2} \left(H_\alpha^{(2)}\right)'(2(-\zeta)^{1/2}) & \pi \zeta^{1/2} \left(H_\alpha^{(1)}\right)'(2(-\zeta)^{1/2}) \end{pmatrix} e^{-\frac{1}{2}\alpha\pi i \sigma_3}. \tag{6.25}$$

Theorem 6.3 *The matrix valued function $\Psi(\zeta)$, defined in* (6.23)–(6.25), *is a solution of the RHP for Ψ.*

Proof. (a) Since the functions I_α, K_α, $H_\alpha^{(1)}$, and $H_\alpha^{(2)}$ (as well as their derivatives) are defined and analytic in the complex plane with a branch cut along the negative real axis, the matrix valued function Ψ defined by (6.23)–(6.25) is analytic in the respective regions.

(b) We need to verify that the jump conditions (6.16)–(6.18) are satisfied. We first verify the jump condition (6.17) on the negative real axis. The Hankel functions evaluated at $2(-\zeta)^{1/2}$ that appear in (6.24) and (6.25) are analytic across the negative ζ-axis. Only the factor $\zeta^{1/2}$ appearing in the second rows of (6.24) and (6.25) has different boundary values on the $+$ and $-$ sides of the negative real axis. Taking this into account, we easily see that the jump condition (6.17) is satisfied.

Next, we check (6.16). For $\zeta \in \gamma_1$ we use (6.23) to evaluate $\Psi_+(\zeta)$ and (6.24) to evaluate $\Psi_-(\zeta)$. From (6.24) the $(1,1)$ entry on the right of (6.16) is

$$e^{\frac{1}{2}\alpha\pi i}\frac{1}{2}\left(H_\alpha^{(1)}(2(-\zeta)^{1/2}) + H_\alpha^{(2)}(2(-\zeta)^{1/2})\right).$$

Using $(-\zeta)^{1/2} = \zeta^{1/2}\exp(-\frac{1}{2}\pi i)$ for $\zeta \in \gamma_1$ and formulas 9.1.3 and 9.1.4 of [2], we find that this is equal to

$$e^{\frac{1}{2}\alpha\pi i}J_\alpha(2\zeta^{1/2}e^{-\frac{1}{2}\pi i}). \tag{6.26}$$

If we now use the fact that, cf. formulas 9.1.35 and 9.6.3 of [2],

$$I_\alpha(z) = e^{\frac{1}{2}\alpha\pi i}J_\alpha(ze^{-\frac{1}{2}\pi i}), \qquad \text{for } -\pi < \arg z < \frac{\pi}{2},$$

we see that (6.26) is equal to $I_\alpha(2\zeta^{1/2})$, and this is the $(1,1)$ entry on the left of (6.16). So the $(1,1)$ entries of both sides of (6.16) agree.

The $(1,2)$ entry on the left of (6.16) is $(i/\pi)K_\alpha(2\zeta^{1/2})$. Using formula 9.6.4 of [2], we rewrite K_α in terms of the Hankel function $H_\alpha^{(2)}$ as follows

$$\frac{i}{\pi}K_\alpha(2\zeta^{1/2}) = \frac{1}{2}\, e^{-\frac{1}{2}\alpha\pi i}H_\alpha^{(2)}(2(-\zeta)^{1/2}).$$

This is exactly the $(1,2)$ entry on the right of (6.17). So the $(1,2)$ entries of both sides (6.16) also agree.

Now we know that the first rows of the left-hand side and the right-hand side of (6.16) are the same. To see that the second rows agree as well, we observe that in both (6.23) and (6.24) (and also (6.25)) the second row is equal to the derivative with respect to ζ of the first row multiplied by the factor $2\pi i\zeta$. Since the jump matrix does not depend on ζ, the equality of the first rows yields the equality of the second rows as well. Thus (6.16) holds. Similar considerations show that (6.18) holds as well.

(c) The behavior near 0 stated in (6.19)–(6.21) follows easily from formulas 9.6.4, 9.6.6, 9.6.7, 9.6.8, 9.6.9, 9.6.26 and 9.6.27 of [2]. □

Having Ψ we define $P^{(1)}(z) = \Psi(n^2 f(z))$ as in (6.22) and $P^{(1)}$ is a solution of the RHP for $P^{(1)}$. Then we define as in (6.10)

$$P(z) = E_n(z)\Psi(n^2 f(z))W(z)^{-\sigma_3}\varphi(z)^{-n\sigma_3}, \tag{6.27}$$

with E_n an analytic matrix valued function in U_{δ_0}. We do not have E_n yet, but no matter how it is chosen, P satisfies parts (a), (b) and (d) of the RHP for P. The multiplication on the left by the analytic factor E_n has no influence on parts (a), (b), and (d). Observe that for part (d) it is important that the matrices in the O-terms in (6.4)–(6.6) are constant along the columns.

We use the freedom we have in choosing E_n to ensure that (6.27) satisfies the matching condition (6.3) of the RHP for P. To that end we need the asymptotic behavior of the

Bessel functions at infinity. Inserting the asymptotics of the modified Bessel functions I_α and K_α as given in formulas 9.7.1–9.7.4 of [2] into (6.23), we find that uniformly as $\zeta \to \infty$ in the sector $|\arg\zeta| < 2\pi/3$,

$$\begin{aligned}\Psi(\zeta) &= \begin{pmatrix} \frac{1}{2\sqrt{\pi}}\zeta^{-1/4}e^{2\zeta^{1/2}}\left(1+O(\zeta^{-1/2})\right) & \frac{i}{2\sqrt{\pi}}\zeta^{-1/4}e^{-2\zeta^{1/2}}\left(1+O(\zeta^{-1/2})\right) \\ \sqrt{\pi}i\zeta^{1/4}e^{2\zeta^{1/2}}\left(1+O(\zeta^{-1/2})\right) & \sqrt{\pi}\zeta^{1/4}e^{-2\zeta^{1/2}}\left(1+O(\zeta^{-1/2})\right) \end{pmatrix} \\ &= \left(2\pi\zeta^{1/2}\right)^{-\sigma_3/2}\frac{1}{\sqrt{2}}\begin{pmatrix} 1+O(\zeta^{-1/2}) & i+O(\zeta^{-1/2}) \\ i+O(\zeta^{-1/2}) & 1+O(\zeta^{-1/2}) \end{pmatrix} e^{2\zeta^{1/2}\sigma_3}. \qquad (6.28)\end{aligned}$$

Inserting the asymptotics of the Hankel functions given in formulas 9.2.3, 9.2.4, 9.2.13, and 9.2.14 of [2] into (6.24) and (6.25), we find that the asymptotics of $\Psi(\zeta)$ in the other two sectors are given by *exactly the same* formula (6.28). Thus (6.28) holds uniformly as $\zeta \to \infty$, $\zeta \in \mathbb{C} \setminus \Sigma_\Psi$. Taking $\zeta = n^2 f(z)$, we then have

$$\Psi(n^2 f(z)) = (2\pi n)^{-\sigma_3/2} f(z)^{-\sigma_3/4}\frac{1}{\sqrt{2}}\begin{pmatrix} 1+O(\frac{1}{n}) & i+O(\frac{1}{n}) \\ i+O(\frac{1}{n}) & 1+O(\frac{1}{n}) \end{pmatrix} e^{2nf^{1/2}(z)\sigma_3}, \qquad (6.29)$$

as $n \to \infty$, uniformly for $z \in \partial U_\delta \setminus \Sigma$. Since $2f^{1/2} = g = \log\phi$ we have $\exp(2nf^{1/2}(z)\sigma_3) = \varphi(z)^{n\sigma_3}$. Combining (6.27) and (6.29) we then get

$$P(z) = E_n(z)\,(2\pi n)^{-\sigma_3/2} f(z)^{-\sigma_3/4}\frac{1}{\sqrt{2}}\begin{pmatrix} 1+O(\frac{1}{n}) & i+O(\frac{1}{n}) \\ i+O(\frac{1}{n}) & 1+O(\frac{1}{n}) \end{pmatrix} W(z)^{-\sigma_3}, \qquad (6.30)$$

as $n \to \infty$, uniformly for $z \in \partial U_\delta \setminus \Sigma$. Since we want P to match with N on ∂U_δ, we now *define* E_n as

$$E_n(z) = N(z)W(z)^{\sigma_3}\frac{1}{\sqrt{2}}\begin{pmatrix} 1 & -i \\ -i & 1 \end{pmatrix} f(z)^{\sigma_3/4}\,(2\pi n)^{\sigma_3/2}. \qquad (6.31)$$

Then E_n is defined and analytic in $U \setminus (-\infty, 1]$. With this E_n, we see from (6.30) that

$$P(z)N^{-1}(z) = N(z)W(z)^{\sigma_3}\left(I + O\left(\frac{1}{n}\right)\right)W(z)^{-\sigma_3}N^{-1}(z), \qquad (6.32)$$

as $n \to \infty$, uniformly for $z \in \partial U_\delta \setminus \Sigma$. Since W as well as all entries of N are uniformly bounded and uniformly bounded away from 0 on ∂U_δ, we get from (6.32) that the matching condition (6.3) is satisfied. It is also clear that E_n is invertible, since by (6.31) E_n is a product of five matrices, all with determinant one, so that

$$\det E_n(z) = 1. \qquad (6.33)$$

Now everything is fine, except for the fact that E_n from (6.31) is defined and analytic on $U \setminus (-\infty, 1]$, but we need it to be analytic in a full neighborhood of 1. We check that E_n has no jumps across the interval $(-1, 1)$, and in addition that it has a removable singularity at 1. To that end, we first determine the behavior of W/D near the point $z = 1$. The lemma states more than what is needed for the proof that E_n is analytic. The extra information will be useful later on.

Lemma 6.4 *For $z \in U_\delta$, we have*

$$\left(\frac{W(z)}{D(z)}\right)^2 = \varphi(z)^{\alpha+\beta} \exp\left((z^2-1)^{1/2} \sum_{n=0}^{\infty} c_n (z-1)^n\right),$$

with coefficients c_n given by (1.11). *In particular, we have that*

$$\frac{W(z)}{D(z)} = 1 + O(|z-1|^{1/2}), \qquad \text{as } z \to 1.$$

Proof. We note that by (5.4)

$$D^2(z) = \frac{(z-1)^\alpha (z+1)^\beta}{\varphi(z)^{\alpha+\beta}} \exp\left(\frac{(z^2-1)^{1/2}}{\pi} \int_{-1}^{1} \frac{\log h(x)}{\sqrt{1-x^2}} \frac{dx}{z-x}\right). \tag{6.34}$$

Let γ be a closed contour in U going around the interval $[-1,1]$ in the positive direction and also encircling the point $z \in U_\delta$. After an easy residue calculation, we then find

$$\frac{1}{\pi} \int_{-1}^{1} \frac{\log h(x)}{\sqrt{1-x^2}} \frac{dx}{z-x} = \frac{\log h(z)}{(z^2-1)^{1/2}} - \frac{1}{2\pi i} \int_\gamma \frac{\log h(\zeta)}{(\zeta^2-1)^{1/2}} \frac{d\zeta}{\zeta - z}.$$

Inserting this in (6.34), we get

$$D^2(z) = \frac{(z-1)^\alpha (z+1)^\beta}{\varphi(z)^{\alpha+\beta}} h(z) \exp\left(-(z^2-1)^{1/2} \frac{1}{2\pi i} \int_\gamma \frac{\log h(\zeta)}{(\zeta^2-1)^{1/2}} \frac{d\zeta}{\zeta-z}\right).$$

Since $W^2(z) = (z-1)^\alpha (z+1)^\beta h(z)$, it then follows that

$$\left(\frac{W(z)}{D(z)}\right)^2 = \varphi(z)^{\alpha+\beta} \exp\left((z^2-1)^{1/2} \frac{1}{2\pi i} \int_\gamma \frac{\log h(\zeta)}{(\zeta^2-1)^{1/2}} \frac{d\zeta}{\zeta-z}\right).$$

Since for $z \in U_\delta$,

$$\frac{1}{2\pi i} \int_\gamma \frac{\log h(\zeta)}{(\zeta^2-1)^{1/2}} \frac{d\zeta}{\zeta - z} = \sum_{n=0}^{\infty} c_n (z-1)^n$$

with coefficients c_n given by formula (1.11), the lemma is proved. □

Proposition 6.5 *The matrix valued function $E_n(z)$ defined in* (6.31) *is analytic in $U \setminus (-\infty, -1]$.*

Proof. We first show that E_n has no jump across the interval $(-1,1)$. Let $x \in (-1,1)$. Since N has the jump (5.1) and $W_+(x)W_-(x) = w(x)$, we have

$$\begin{aligned} N_+(x) W_+(x)^{\sigma_3} &= N_-(x) \begin{pmatrix} 0 & w(x) \\ -w(x)^{-1} & 0 \end{pmatrix} \left(\frac{w(x)}{W_-(x)}\right)^{\sigma_3} \\ &= N_-(x) \begin{pmatrix} 0 & W_-(x) \\ -W_-(x)^{-1} & 0 \end{pmatrix} \\ &= N_-(x) W_-^{\sigma_3}(x) \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}. \end{aligned} \tag{6.35}$$

Furthermore, we have that $f(x)$ is negative, and taking fourth roots, we get $f_+(x)^{1/4} = if_-(x)^{1/4}$, so that

$$f_+(x)^{\sigma_3/4} = \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix} f_-(x)^{\sigma_3/4}. \tag{6.36}$$

By (6.31), (6.35), and (6.36) we then have for $x \in (-1,1)$,

$$\begin{aligned}(E_n)_+(x) &= N_+(x)W_+(x)^{\sigma_3}\frac{1}{\sqrt{2}}\begin{pmatrix} 1 & -i \\ -i & 1 \end{pmatrix} f_+(x)^{\sigma_3/4}(2\pi n)^{\sigma_3/2} \\ &= N_-(x)W_-(x)^{\sigma_3}\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}\frac{1}{\sqrt{2}}\begin{pmatrix} 1 & -i \\ -i & 1 \end{pmatrix}\begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix} f_-(x)^{\sigma_3/4}(2\pi n)^{\sigma_3/2} \\ &= N_-(x)W_-(x)^{\sigma_3}\frac{1}{\sqrt{2}}\begin{pmatrix} 1 & -i \\ -i & 1 \end{pmatrix} f_-(x)^{\sigma_3/4}(2\pi n)^{\sigma_3/2} \\ &= (E_n)_-(x).\end{aligned}$$

Therefore E_n is analytic across $(-1,1)$.

Next, we have to show that E_n has a removable singularity at 1. Using Lemma 6.4 and (5.5) we see that

$$\begin{aligned}N(z)W(z)^{\sigma_3} &= D_\infty^{\sigma_3}\begin{pmatrix} \frac{a(z)+a(z)^{-1}}{2} & \frac{a(z)-a(z)^{-1}}{2i} \\ \frac{a(z)-a(z)^{-1}}{-2i} & \frac{a(z)+a(z)^{-1}}{2} \end{pmatrix}\left(\frac{W(z)}{D(z)}\right)^{\sigma_3} \\ &= O\begin{pmatrix} |z-1|^{-1/4} & |z-1|^{-1/4} \\ |z-1|^{-1/4} & |z-1|^{-1/4} \end{pmatrix} O\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \qquad \text{as } z \to 1. \end{aligned} \tag{6.37}$$

Since f has a simple zero at 1 we also have

$$f(z)^{\sigma_3/4} = O\begin{pmatrix} |z-1|^{1/4} & 0 \\ 0 & |z-1|^{-1/4} \end{pmatrix}, \qquad \text{as } z \to 1. \tag{6.38}$$

Thus by (6.31), (6.37), and (6.38) we have that all entries of $E_n(z)$ have at most a square-root singularity at $z = 1$. Since we already know that E_n is analytic in a punctured neighborhood of 1, the isolated singularity at 1 is removable. Thus, E_n is analytic in $U \setminus (-\infty, -1]$. □

The construction of the parametrix P near $z = 1$ is now completed. A similar construction based on Bessel functions of order β yields a parametrix $\tilde{P}$ defined in a neighborhood $\tilde{U}_\delta = \{z \mid |z+1| < \delta\}$ of $z = -1$ that satisfies the following RHP.

RHP for $\tilde{P}$:

(a) $\tilde{P}(z)$ is defined and analytic for $z \in \tilde{U}_{\delta_0} \setminus \Sigma$ for some $\delta_0 > \delta$.

(b) $\tilde{P}(z)$ satisfies the following jump relations on $\tilde{U}_\delta \cap \Sigma^o$:

$$\tilde{P}_+(z) = \tilde{P}_-(z)\begin{pmatrix} 1 & 0 \\ w(z)^{-1}\varphi(z)^{-2n} & 1 \end{pmatrix}, \qquad \text{for } z \in \tilde{U}_\delta \cap (\Sigma_1^o \cup \Sigma_3^o), \tag{6.39}$$

$$\tilde{P}_+(x) = \tilde{P}_-(x)\begin{pmatrix} 0 & w(x) \\ -w(x)^{-1} & 0 \end{pmatrix}, \qquad \text{for } x \in \tilde{U}_\delta \cap \Sigma_2^o. \tag{6.40}$$

(c) On $\partial\tilde{U}_\delta$ we have, as $n \to \infty$

$$\tilde{P}(z)N^{-1}(z) = I + O\left(\frac{1}{n}\right), \qquad \text{uniformly for } z \in \partial\tilde{U}_\delta \setminus \Sigma. \tag{6.41}$$

(d) For $\beta < 0$, the matrix function $\tilde{P}(z)$ has the following behavior as $z \to -1$:

$$\tilde{P}(z) = O\begin{pmatrix} 1 & |z+1|^\beta \\ 1 & |z+1|^\beta \end{pmatrix}, \qquad \text{as } z \to -1, z \in \tilde{U}_\delta \setminus \Sigma.$$

For $\beta = 0$, $\tilde{P}(z)$ has the following behavior as $z \to -1$:

$$\tilde{P}(z) = O\begin{pmatrix} \log|z+1| & \log|z+1| \\ \log|z+1| & \log|z+1| \end{pmatrix}, \qquad \text{as } z \to -1, z \in \tilde{U}_\delta \setminus \Sigma.$$

For $\beta > 0$, $\tilde{P}(z)$ has the following behavior as $z \to -1$:

$$\tilde{P}(z) = \begin{cases} O\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}, & \text{as } z \to -1 \text{ outside the lens,} \\ O\begin{pmatrix} |z+1|^{-\beta} & 1 \\ |z+1|^{-\beta} & 1 \end{pmatrix}, & \text{as } z \to -1 \text{ inside the lens.} \end{cases}$$

Details of the construction of $\tilde{P}$ are as follows. Instead of working with φ it is more convenient to introduce

$$\tilde{\varphi}(z) = \varphi(-z) = -\varphi(z), \tag{6.42}$$

which is defined and analytic in $\mathbb{C} \setminus [-1,1]$. Replacing φ by $\tilde{\varphi}$ does not change the jump matrix in (6.39). Since $\varphi_+(x)\varphi_-(x) = 1$ for $x \in (-1,1)$ it is obvious that we also have

$$\tilde{\varphi}_+(x)\tilde{\varphi}_-(x) = 1, \qquad \text{for } x \in (-1,1). \tag{6.43}$$

The function

$$\tilde{W}(z) = \left((1-z)^\alpha(-1-z)^\beta h(z)\right)^{1/2}, \qquad \text{for } z \in U \setminus [-1,\infty), \tag{6.44}$$

is analytic in $U \setminus [-1,\infty)$, and satisfies

$$\tilde{W}^2(z) = \begin{cases} e^{-\beta\pi i}w(z), & \text{for } \operatorname{Im} z > 0, \\ e^{\beta\pi i}w(z), & \text{for } \operatorname{Im} z < 0. \end{cases} \tag{6.45}$$

Thus in particular, $\tilde{W}_\pm^2(x) = e^{\mp\beta\pi i}w(x)$ for $x \in (-1,1)$, and so

$$\tilde{W}_+(x)\tilde{W}_-(x) = w(x), \qquad \text{for } x \in (-1,1). \tag{6.46}$$

Writing

$$\tilde{P}(z) = \tilde{E}_n(z)\tilde{P}^{(1)}(z)\tilde{W}(z)^{-\sigma_3}\tilde{\varphi}(z)^{-n\sigma_3}, \tag{6.47}$$

with an invertible analytic factor $\tilde{E}_n$, we see, using (6.39), (6.40), (6.43), (6.45) and (6.46), that $\tilde{P}^{(1)}$ should satisfy the following RHP.

RHP for $\tilde{P}^{(1)}$:

(a) $\tilde{P}^{(1)}(z)$ is defined and analytic for $z \in \tilde{U}_{\delta_0} \setminus \Sigma$ for some $\delta_0 > \delta$.

(b) $\tilde{P}^{(1)}(z)$ satisfies the following jump relations:

$$\begin{cases} \tilde{P}^{(1)}_+(z) = \tilde{P}^{(1)}_-(z) \begin{pmatrix} 1 & 0 \\ e^{-\beta\pi i} & 1 \end{pmatrix}, & \text{for } z \in \tilde{U}_\delta \cap \Sigma_1^o, \\ \tilde{P}^{(1)}_+(x) = \tilde{P}^{(1)}_-(x) \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, & \text{for } x \in \tilde{U}_\delta \cap \Sigma_2^o, \\ \tilde{P}^{(1)}_+(z) = \tilde{P}^{(1)}_-(z) \begin{pmatrix} 1 & 0 \\ e^{\beta\pi i} & 1 \end{pmatrix}, & \text{for } z \in \tilde{U}_\delta \cap \Sigma_3^o. \end{cases} \tag{6.48}$$

(c) For $\beta < 0$, the matrix function $\tilde{P}^{(1)}(z)$ has the following behavior as $z \to -1$:

$$\tilde{P}^{(1)}(z) = O\begin{pmatrix} |z+1|^{\beta/2} & |z+1|^{\beta/2} \\ |z+1|^{\beta/2} & |z+1|^{\beta/2} \end{pmatrix}, \qquad \text{as } z \to -1, z \in \tilde{U}_\delta \setminus \Sigma.$$

For $\beta = 0$, $\tilde{P}^{(1)}(z)$ has the following behavior as $z \to -1$:

$$\tilde{P}^{(1)}(z) = O\begin{pmatrix} \log|z+1| & \log|z+1| \\ \log|z+1| & \log|z+1| \end{pmatrix}, \qquad \text{as } z \to -1, z \in \tilde{U}_\delta \setminus \Sigma.$$

For $\beta > 0$, $\tilde{P}^{(1)}(z)$ has the following behavior as $z \to -1$:

$$\tilde{P}^{(1)}(z) = \begin{cases} O\begin{pmatrix} |z+1|^{\beta/2} & |z+1|^{-\beta/2} \\ |z+1|^{\beta/2} & |z+1|^{-\beta/2} \end{pmatrix}, & \text{as } z \to -1 \text{ outside the lens}, \\ O\begin{pmatrix} |z+1|^{-\beta/2} & |z+1|^{-\beta/2} \\ |z+1|^{-\beta/2} & |z+1|^{-\beta/2} \end{pmatrix}, & \text{as } z \to -1 \text{ inside the lens}. \end{cases}$$

The jumps (6.48) of $\tilde{P}^{(1)}$ are analogous to the jumps (6.11) of $P^{(1)}$. To construct $\tilde{P}^{(1)}$ we first define a function $\tilde{g}$ as

$$\tilde{g}(z) = \log \tilde{\varphi}(z), \qquad \text{for } z \in \mathbb{C} \setminus [-1, \infty). \tag{6.49}$$

and a function $\tilde{f}$ by

$$\tilde{f}(z) = \tilde{g}^2(z)/4, \qquad \text{for } z \in \tilde{U}_\delta \setminus [-1, \infty). \tag{6.50}$$

Then $\zeta = \tilde{f}(z)$ is a one-to-one conformal mapping of $\tilde{U}_\delta$ onto a neighborhood of $\zeta = 0$. However the ordering is reversed. Thus if $z < -1$, then $\zeta > 0$, while if $z > -1$, then $\zeta < 0$. The contours Σ_1 and Σ_3 are chosen such that $\tilde{f}(\Sigma_1 \cap \tilde{U}_\delta)$ is part of the ray γ_3, and $\tilde{f}(\Sigma_3 \cap \tilde{U}_\delta)$ is part of the ray γ_1 in the ζ-plane.

Then we need a fixed matrix function $\tilde{\Psi}$ defined in the complex ζ-plane that satisfies the following RHP on the contour $\Sigma_{\tilde{\Psi}}$ shown in Figure 5.

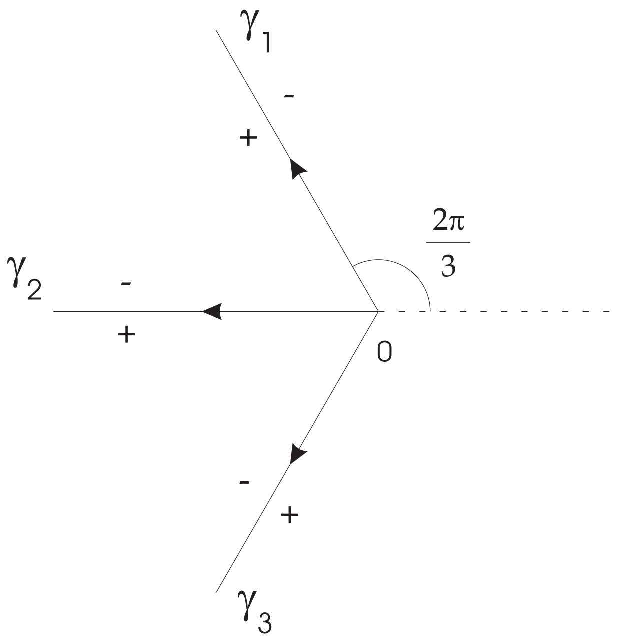

Figure 5: The contour $\Sigma_{\tilde{\Psi}}$

RHP for $\tilde{\mathbf{\Psi}}$:

(a) $\tilde{\Psi}(\zeta)$ is analytic for $\zeta \in \mathbb{C} \setminus \Sigma_{\tilde{\Psi}}$.

(b) $\tilde{\Psi}(\zeta)$ satisfies the following jump relations:

$$\begin{aligned}
\tilde{\Psi}_+(\zeta) &= \tilde{\Psi}_-(\zeta) \begin{pmatrix} 1 & 0 \\ e^{\beta\pi i} & 1 \end{pmatrix}, \qquad \text{for } \zeta \in \gamma_1, \\
\tilde{\Psi}_+(\zeta) &= \tilde{\Psi}_-(\zeta) \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \qquad \text{for } \zeta \in \gamma_2, \\
\tilde{\Psi}_+(\zeta) &= \tilde{\Psi}_-(\zeta) \begin{pmatrix} 1 & 0 \\ e^{-\beta\pi i} & 1 \end{pmatrix}, \qquad \text{for } \zeta \in \gamma_3.
\end{aligned}$$

(c) $\tilde{\Psi}(\zeta)$ has the same behavior as $\Psi(\zeta)$ near $\zeta = 0$, if we replace α by β.

When comparing this RHP with (6.16)–(6.18) we have to realize that the *directions on the contours are reversed*. The reversal of the directions is taken care of by conjugating with the Pauli matrix σ_3. Thus we take

$$\tilde{\Psi}(\zeta) = \sigma_3 \Psi(\zeta; \alpha \to \beta) \sigma_3, \tag{6.51}$$

where $\Psi(\cdot; \alpha \to \beta)$ is the matrix valued function defined by (6.23)–(6.25), but with Bessel functions of order β instead of order α. Then $\tilde{P}^{(1)}(z) = \tilde{\Psi}(n^2 \tilde{f}(z))$ is a solution of the RHP for $\tilde{P}^{(1)}$ and thus

$$\tilde{P}(z) = \tilde{E}_n(z) \tilde{\Psi}(n^2 \tilde{f}(z)) \tilde{\varphi}(z)^{-n\sigma_3} \tilde{W}(z)^{-\sigma_3}, \tag{6.52}$$

with $\tilde{E}_n$ an analytic matrix valued function, satisfies the parts (a), (b), and (d) of the RHP for $\tilde{P}$. As before we construct the analytic factor $\tilde{E}_n$ so that the matching condition (c) is satisfied as well. We define $\tilde{E}_n$ by

$$\tilde{E}_n(z) = N(z)\tilde{W}(z)^{\sigma_3}\frac{1}{\sqrt{2}}\begin{pmatrix}1 & i\\ i & 1\end{pmatrix}\tilde{f}(z)^{\sigma_3/4}\,(2\pi n)^{\sigma_3/2}\,, \quad \text{for } z \in \tilde{U}_\delta. \tag{6.53}$$

Similar reasoning as before shows that $\tilde{E}_n$ is analytic in $U \setminus [1,\infty)$, and that the matching condition is satisfied.

This completes the construction of the local parametrix $\tilde{P}$ near -1. Note the slight difference (apart from the tildes) between $\tilde{E}_n$ defined in (6.53) and E_n defined in (6.31).

For later use, we remark that the following analogue of Lemma 6.4 holds. Its proof is similar.

Lemma 6.6 *For $z \in \tilde{U}_\delta$, we have*

$$\left(\frac{\tilde{W}(z)}{D(z)}\right)^2 = \tilde{\varphi}(z)^{\alpha+\beta}\exp\left((z^2-1)^{1/2}\sum_{n=0}^{\infty} d_n(z+1)^n\right),$$

with coefficients d_n given by (1.12).

7 Third transformation $S \mapsto R$

In the final transformation of our original problem we define the matrix valued function R by

$$R(z) = S(z)N^{-1}(z), \qquad \text{for } z \in \mathbb{C} \setminus (\overline{U}_\delta \cup \overline{\tilde{U}}_\delta \cup \Sigma), \tag{7.1}$$

$$R(z) = S(z)P^{-1}(z), \qquad \text{for } z \in U_\delta \setminus \Sigma, \tag{7.2}$$

$$R(z) = S(z)\tilde{P}^{-1}(z), \qquad \text{for } z \in \tilde{U}_\delta \setminus \Sigma. \tag{7.3}$$

Remark 7.1 The inverses of the matrices N, P, and $\tilde{P}$ used in (7.1)–(7.3) exist, since the determinants of these matrices are equal to 1. For N, this is easy to see from its definition (5.5). To see this for P, we note that by (6.27) and (6.33) it is sufficient to show that $\det\Psi(\zeta) = 1$ for $\zeta \in \mathbb{C} \setminus \Sigma_\Psi$. It is clear that $\det\Psi(\zeta)$ is analytic in $\mathbb{C} \setminus \Sigma_\Psi$. Since the jump matrices in (6.17)–(6.18) have determinant one, it follows that $\det\Psi(\zeta)$ has an analytic continuation to $\mathbb{C} \setminus \{0\}$. By (6.19)–(6.21), the behavior of $\det\Psi(\zeta)$ as $\zeta \to 0$ is

$$\det\Psi(\zeta) = \begin{cases} O\left(|\zeta|^{\alpha}\right), & \text{if } \alpha < 0,\\ O\left((\log|\zeta|)^2\right), & \text{if } \alpha = 0,\\ O(1), & \text{if } \alpha > 0 \text{ and } |\arg(\zeta)| < 2\pi/3,\\ O(|\zeta|^{-\alpha}) & \text{if } \alpha > 0 \text{ and } 2\pi/3 < |\arg(\zeta)| < \pi. \end{cases}$$

Then the singularity at 0 is removable, which is obvious in case $\alpha \le 0$, and which follows as in the proof of Lemma 4.1 in the paragraph after formula (4.13) in case $\alpha > 0$.

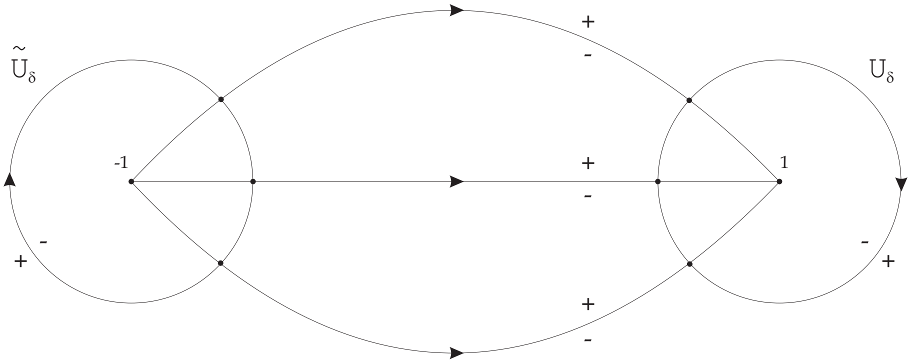

Figure 6: System of contours for R

Thus $\det \Psi(\zeta)$ is entire. From the asymptotics at infinity, given in (6.28), we see that $\det \Psi(\zeta) \to 1$ as $\zeta \to \infty$. By Liouville's theorem we then find that $\det \Psi(\zeta) = 1$ for every ζ. As already noted this implies that $\det P(z) = 1$. In the same way, it follows that $\det \tilde{P}(z) = 1$.

Now R given by (7.1)–(7.3) is defined and analytic in $\mathbb{C} \setminus (\Sigma \cup \partial U_\delta \cup \partial \tilde{U}_\delta)$. Then R has jumps on a system of contours shown in Figure 6. However, since by construction the jumps of S and N on the interval $(-1+\delta, 1-\delta)$ agree, it follows from (7.1) that R has the identity as jump matrix on this interval, and so has an analytic continuation to $(-1+\delta, 1-\delta)$. Also, since the jumps of S and P on $U_\delta \cap \Sigma^o$ are exactly the same, it follows from (7.2) that R has an analytic continuation across these contours as well. Similarly, it follows from (7.3) that R is analytic across $\tilde{U}_\delta \cap \Sigma^o$. What remains are the jumps on a reduced system of contours, which we will call Σ_R, see Figure 7, and possible isolated singularities at ±1. We prove that these singularities are removable.

If $\alpha < 0$, we use the fact that $\det P(z) = 1$, and (6.4) to conclude that

$$P^{-1}(z) = O\begin{pmatrix} |z-1|^\alpha & |z-1|^\alpha \\ 1 & 1 \end{pmatrix}, \qquad \text{as } z \to 1.$$

Then from (4.6) and (7.2) it follows that

$$R(z) = O\begin{pmatrix} |z-1|^\alpha & |z-1|^\alpha \\ |z-1|^\alpha & |z-1|^\alpha \end{pmatrix}, \qquad \text{as } z \to 1.$$

Since R is analytic in $U_\delta \setminus \{1\}$ and $\alpha > -1$, it follows that the singularity at 1 is removable.

If $\alpha = 0$, it follows in a similar way from (4.7), (6.5), and (7.2) that

$$R(z) = O\begin{pmatrix} (\log|z-1|)^2 & (\log|z-1|)^2 \\ (\log|z-1|)^2 & (\log|z-1|)^2 \end{pmatrix}, \qquad \text{as } z \to 1,$$

from which it also follows that the singularity at 1 is removable.

And finally, if $\alpha > 0$, it follows from (4.8), (6.6), and (7.2) that

$$R(z) = \begin{cases} O\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}, & \text{as } z \to 1 \text{ outside the lens,} \\ O\begin{pmatrix} |z-1|^{-\alpha} & |z-1|^{-\alpha} \\ |z-1|^{-\alpha} & |z-1|^{-\alpha} \end{pmatrix}, & \text{as } z \to 1 \text{ inside the lens.} \end{cases}$$

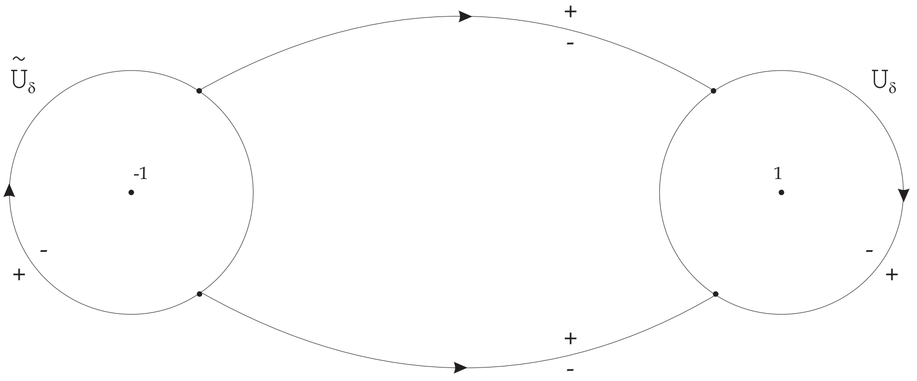

Figure 7: Reduced system of contours Σ_R

From this it also follows that the singularity at 1 is removable, cf. the argument given after formula (4.13) in Lemma 4.1.

So in all cases we proved that the singularity at 1 is removable. Similarly it follows that the singularity at -1 is removable. Hence R is analytic in $\mathbb{C} \setminus \Sigma_R$, where

$$\Sigma_R = \partial U_\delta \cup \partial \tilde{U}_\delta \cup \left((\Sigma_1 \cup \Sigma_3) \setminus (U_\delta \cup \tilde{U}_\delta) \right).$$

The contour Σ_R is oriented as indicated in Figure 7.

We next calculate the jumps of R. For $z \in \Sigma_R \setminus (\partial U_\delta \cup \partial \tilde{U}_\delta)$, we use (4.3) and (7.1) to obtain

$$\begin{aligned} R_+(z) &= S_+(z) N^{-1}(z) = S_-(z) \begin{pmatrix} 1 & 0 \\ w(z)^{-1}\varphi(z)^{-2n} & 1 \end{pmatrix} N^{-1}(z) \\ &= R_-(z) N(z) \begin{pmatrix} 1 & 0 \\ w(z)^{-1}\varphi(z)^{-2n} & 1 \end{pmatrix} N^{-1}(z). \end{aligned}$$

On the boundary of U_δ we have $R_+(z) = S(z)N^{-1}(z)$ and $R_-(z) = S(z)P^{-1}(z)$ so that

$$R_+(z) = R_-(z)P(z)N^{-1}(z), \qquad \text{for } z \in \partial U_\delta.$$

Similarly, on the boundary of $\tilde{U}_\delta$ we have

$$R_+(z) = R_-(z)\tilde{P}(z)N^{-1}(z), \qquad \text{for } z \in \partial \tilde{U}_\delta.$$

So we see that R is a solution of the following RHP:

RHP for *R*:

(a) $R(z)$ is analytic for $z \in \mathbb{C} \setminus \Sigma_R$.

(b) $R(z)$ satisfies the following jump relations on Σ_R:

$$R_+(z) = R_-(z)P(z)N^{-1}(z), \qquad \text{for } z \in \partial U_\delta, \tag{7.4}$$

$$R_+(z) = R_-(z)\tilde{P}(z)N^{-1}(z), \qquad \text{for } z \in \partial \tilde{U}_\delta, \tag{7.5}$$

$$R_+(z) = R_-(z)N(z) \begin{pmatrix} 1 & 0 \\ w(z)^{-1}\varphi(z)^{-2n} & 1 \end{pmatrix} N^{-1}(z), \tag{7.6}$$

$$\text{for } z \in \Sigma_R \setminus (\partial U_\delta \cup \partial \tilde{U}_\delta).$$

(c) $R(z) = I + O\left(\frac{1}{z}\right), \qquad \text{as } z \to \infty.$

Remark 7.2 Since $\log|\varphi(z)| > c > 0$ on the upper and lower lips of Σ_R and $N(z)$ does not depend on n, the jump matrix in (7.6) tends to the identity matrix at an exponential rate

$$R_+(z) = R_-(z)\left(I + O\left(e^{-2cn}\right)\right), \qquad \text{as } n \to \infty \tag{7.7}$$

uniformly on $\Sigma_R \setminus (\partial U_\delta \cup \partial\tilde{U}_\delta)$. By (6.3) and (7.4) we have on the boundary of U_δ as $n \to \infty$ that

$$R_+(z) = R_-(z)\left(I + O\left(\frac{1}{n}\right)\right), \qquad \text{as } n \to \infty, \tag{7.8}$$

uniformly on ∂U_δ. At the two points where ∂U_δ intersects with the arcs Σ_1 and Σ_3, the boundary values are taken within a single connected component of $\mathbb{C} \setminus \Sigma_R$. Since R is continuous up to the boundary from within each component, (7.8) holds everywhere on ∂U_δ. Similarly by (6.41) and (7.5)

$$R_+(z) = R_-(z)\left(I + O\left(\frac{1}{n}\right)\right), \qquad \text{as } n \to \infty, \tag{7.9}$$

uniformly on $\partial\tilde{U}_\delta$. From (7.7)–(7.9) it follows as in [11] that

$$R(z) = I + O\left(\frac{1}{n}\right), \qquad \text{as } n \to \infty \text{ uniformly on } \mathbb{C} \setminus \Sigma_R, \tag{7.10}$$

The relation (7.10) is the main term in the asymptotics for R and it is enough to give the leading term in the asymptotics of the orthogonal polynomials. In the next section we will give a complete asymptotic expansion for R.

8 Asymptotics for $R(z)$

8.1 Asymptotic expansion for Δ

We write the jump matrix for R in the form $I + \Delta(s)$, so that by (7.4)–(7.6)

$$I + \Delta(s) = \begin{cases} P(s)N^{-1}(s), & \text{for } s \in \partial U_\delta, \\ \tilde{P}(s)N^{-1}(s), & \text{for } s \in \partial\tilde{U}_\delta, \\ N(s)\begin{pmatrix} 1 & 0 \\ w^{-1}(s)\varphi(s)^{-2n} & 1 \end{pmatrix} N^{-1}(s), & \text{for } s \in \Sigma_R \setminus (\partial U_\delta \cup \partial\tilde{U}_\delta). \end{cases} \tag{8.1}$$

We show that Δ has an asymptotic expansion in powers of $1/n$ of the form

$$\Delta(s) \sim \sum_{k=1}^{\infty} \frac{\Delta_k(s)}{n^k} \qquad \text{as } n \to \infty, \tag{8.2}$$

uniformly for $s \in \Sigma_R$. On $\Sigma_R \setminus (\partial U_\delta \cup \partial \tilde{U}_\delta)$, the jump matrix is the identity matrix plus an exponentially small term, so that for every $k \in \mathbb{N}$,

$$\Delta_k(s) = 0, \qquad \text{for } s \in \Sigma_R \setminus \left(\partial U_\delta \cup \partial \tilde{U}_\delta\right). \tag{8.3}$$

We now determine $\Delta_k(s)$ for $s \in \partial U_\delta$. The modified Bessel functions $I_\alpha(\zeta)$, $K_\alpha(\zeta)$, and their derivatives, have an asymptotic expansion as $\zeta \to \infty$, see formulas 9.7.1–9.7.4 of [2]. Using this expansion in (6.23), we find that

$$\begin{aligned} \Psi(\zeta) \;=\;& (2\pi)^{-\sigma_3/2}\zeta^{-\sigma_3/4}\frac{1}{\sqrt{2}}\begin{pmatrix} 1 & i \\ i & 1 \end{pmatrix} \\ & \left[I + \sum_{k=1}^{\infty} \frac{(\alpha, k-1)}{4^k \zeta^{k/2}} \begin{pmatrix} \frac{(-1)^k}{k}(\alpha^2 + \frac{1}{2}k - \frac{1}{4}) & -(k-\frac{1}{2})i \\ (-1)^k(k-\frac{1}{2})i & \frac{1}{k}(\alpha^2 + \frac{1}{2}k - \frac{1}{4}) \end{pmatrix}\right] e^{2\zeta^{1/2}\sigma_3} \end{aligned} \tag{8.4}$$

as $\zeta \to \infty$, uniformly in the sector $|\arg \zeta| < 2\pi/3$. Here $(\alpha, 0) = 1$ and

$$(\alpha, k) = \frac{(4\alpha^2 - 1)(4\alpha^2 - 9)\cdots(4\alpha^2 - (2k-1)^2)}{2^{2k}k!},$$

see also e.g. [3, §4.9,§4.12]. Inserting the asymptotic expansions of the Hankel functions into (6.24) and (6.25), we obtain the same formula (8.4) as $\zeta \to \infty$ in the other sectors. Thus (8.4) is valid uniformly as $\zeta \to \infty$. Then by a calculation using (6.12), (6.13), (6.27), (6.31), and (8.1), we find that uniformly for $s \in \partial U_\delta$,

$$\begin{aligned} \Delta(s) \;&=\; P(s)N^{-1}(s) - I \\ &\sim\; N(s)W(s)^{\sigma_3}\left[\sum_{k=1}^{\infty} \frac{(\alpha, k-1)}{n^k 2^k g(s)^k} \begin{pmatrix} \frac{(-1)^k}{k}(\alpha^2 + \frac{1}{2}k - \frac{1}{4}) & -(k-\frac{1}{2})i \\ (-1)^k(k-\frac{1}{2})i & \frac{1}{k}(\alpha^2 + \frac{1}{2}k - \frac{1}{4}) \end{pmatrix}\right] \\ &\quad\; W(s)^{-\sigma_3}N^{-1}(s). \end{aligned}$$

Thus,

$$\begin{aligned} \Delta_k(s) \;=\;& \frac{(\alpha, k-1)}{2^k g(s)^k} N(s)W(s)^{\sigma_3} \begin{pmatrix} \frac{(-1)^k}{k}(\alpha^2 + \frac{1}{2}k - \frac{1}{4}) & -(k-\frac{1}{2})i \\ (-1)^k(k-\frac{1}{2})i & \frac{1}{k}(\alpha^2 + \frac{1}{2}k - \frac{1}{4}) \end{pmatrix} \\ & W(s)^{-\sigma_3}N^{-1}(s), \qquad \text{for } s \in \partial U_\delta, \end{aligned} \tag{8.5}$$

Analogously, using (6.49)–(6.53), and (8.1), we find

$$\begin{aligned} \Delta_k(s) \;=\;& \frac{(\beta, k-1)}{2^k \tilde{g}(s)^k} N(s)\tilde{W}(s)^{\sigma_3} \begin{pmatrix} \frac{(-1)^k}{k}(\beta^2 + \frac{1}{2}k - \frac{1}{4}) & (k-\frac{1}{2})i \\ (-1)^{k+1}(k-\frac{1}{2})i & \frac{1}{k}(\alpha^2 + \frac{1}{2}k - \frac{1}{4}) \end{pmatrix} \\ & \tilde{W}(s)^{-\sigma_3}N^{-1}(s), \qquad \text{for } s \in \partial \tilde{U}_\delta. \end{aligned} \tag{8.6}$$

To summarize, we have shown

Lemma 8.1 *$\Delta(s)$ has an asymptotic expansion in powers of $1/n$ of the form (8.2), which is valid uniformly for $s \in \Sigma_R$. For $s \in \Sigma_R \setminus (\partial U_\delta \cup \partial \tilde{U}_\delta)$, we have $\Delta_k(s) = 0$ for every k. For $s \in \partial U_\delta$ and $s \in \partial \tilde{U}_\delta$, we have that Δ_k is given by (8.5)–(8.6), respectively.*

For later use, we need

Lemma 8.2 (a) *For every $k \in \mathbb{N}$, the restriction of Δ_k to ∂U_δ has a meromorphic continuation to a neighborhood U_{δ_0} of 1 for some $\delta_0 > \delta$. The continuation is analytic, except at 1, where it has a pole of order at most $[(k+1)/2]$.*

(b) *For every $k \in \mathbb{N}$, the restriction of Δ_k to $\partial \tilde{U}_\delta$ has a meromorphic continuation to a neighborhood $\tilde{U}_{\delta_0}$ of -1 for some $\delta_0 > \delta$. The continuation is analytic, except at -1, where it has a pole of order at most $[(k+1)/2]$.*

Proof. (a) The formula (8.5) shows that Δ_k is analytic on $U \setminus (-\infty, 1]$. We recall, see (6.35), that for $x \in (-1,1)$,

$$N_+(x)W_+(x)^{\sigma_3} = N_-(x)W_-(x)^{\sigma_3}\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.$$

Since $g_+(x) = -g_-(x)$, we then have for $x \in (-1,1)$,

$$\begin{aligned} \Delta_{k,+}(x) &= (-1)^k \frac{(\alpha, k-1)}{2^k g_-(x)^k} N_-(x)W_-(x)^{\sigma_3} \\ &\qquad \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \begin{pmatrix} \frac{(-1)^k}{k}(\alpha^2 + \frac{1}{2}k - \frac{1}{4}) & -(k-\frac{1}{2})i \\ (-1)^k (k-\frac{1}{2})i & \frac{1}{k}(\alpha^2+\frac{1}{2}k-\frac{1}{4}) \end{pmatrix} \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \\ &\qquad W_-(x)^{-\sigma_3} N_-^{-1}(x) \\ &= (-1)^k \frac{(\alpha, k-1)}{2^k g_-(x)^k} N_-(x)W_-(x)^{\sigma_3} \\ &\qquad (-1)^k \begin{pmatrix} \frac{(-1)^k}{k}(\alpha^2 + \frac{1}{2}k - \frac{1}{4}) & -(k-\frac{1}{2})i \\ (-1)^k (k-\frac{1}{2})i & \frac{1}{k}(\alpha^2+\frac{1}{2}k-\frac{1}{4}) \end{pmatrix} \\ &\qquad W_-(x)^{-\sigma_3} N_-^{-1}(x) \\ &= \Delta_{k,-}(x). \end{aligned}$$

Thus Δ_k is analytic across $(-1,1)$.

To determine the behavior near 1, we note that $g(z) = O(|z-1|^{1/2})$ as $z \to 1$, and

$$N(z)W(z)^{\sigma_3} = O\begin{pmatrix} |z-1|^{-1/4} & |z-1|^{-1/4} \\ |z-1|^{-1/4} & |z-1|^{-1/4} \end{pmatrix},$$

as $z \to 1$, see (6.37). Thus we have by formula (8.5),

$$\Delta_k(z) = O\begin{pmatrix} |z-1|^{-\frac{k}{2}-\frac{1}{2}} & |z-1|^{-\frac{k}{2}-\frac{1}{2}} \\ |z-1|^{-\frac{k}{2}-\frac{1}{2}} & |z-1|^{-\frac{k}{2}-\frac{1}{2}} \end{pmatrix}, \qquad \text{as } z \to 1.$$

Since $z = 1$ is an isolated singularity of $\Delta_k(z)$, it then follows that $z = 1$ is a pole of order at most $[(k+1)/2]$. This proves part (a).

Part (b) is proved similarly. □

8.2 Asymptotic expansion for R

As in Theorem 7.10 of [11] we obtain from (8.2) that R has an asymptotic expansion of the form

$$R(z) \sim I + \sum_{k=1}^{\infty} \frac{R_k(z)}{n^k}, \qquad \text{as } n \to \infty, \tag{8.7}$$

which is valid uniformly for $z \in \mathbb{C} \setminus (\partial U_\delta \cup \partial \tilde{U}_\delta)$. We have that

$$R_k(z) \text{ is analytic for } z \in \mathbb{C} \setminus (\partial U_\delta \cup \partial \tilde{U}_\delta), \tag{8.8}$$

and

$$R_k(z) = O\left(\frac{1}{z}\right), \qquad \text{as } z \to \infty. \tag{8.9}$$

The expansion (8.7) is valid uniformly near infinity in the following sense.

Lemma 8.3 *For every l there exists a constant $C > 0$, such that for every z with $|z| \geq 2$,*

$$\left\| R(z) - I - \sum_{k=1}^{l} \frac{R_k(z)}{n^k} \right\| \leq \frac{C}{|z| n^{l+1}}. \tag{8.10}$$

Here $\| \cdot \|$ denotes any matrix norm.

Proof. From $R_+ = R_- + R_-\Delta$ we obtain the following integral representation for R (cf. the discussion in the proof of Theorem 7.8 in [11]),

$$R(z) = I + \frac{1}{2\pi i} \int_{\Sigma_R} \frac{R_-(s)\Delta(s)}{s-z}\, ds, \qquad \text{for } z \in \mathbb{C} \setminus \Sigma_R. \tag{8.11}$$

Expanding the jump relation $R_+ = R_-(I+\Delta)$ using (8.2) and (8.7), and collecting powers of $1/n$, we find for $k = 1, 2, \ldots$,

$$R_{k,+}(s) - R_{k,-}(s) = \sum_{j=1}^{k} R_{k-j,-}(s)\Delta_j(s), \qquad \text{for } s \in \partial U_\delta \cup \partial \tilde{U}_\delta, \tag{8.12}$$

where $R_{0,-} = I$. From the Sokhotskii-Plemelj formula, (8.3), and (8.9) it then follows that

$$R_k(z) = \frac{1}{2\pi i} \int_{\Sigma_R} \sum_{j=1}^{k} R_{k-j,-}(s)\Delta_j(s) \frac{ds}{s-z}, \qquad \text{for } z \in \mathbb{C} \setminus \Sigma_R. \tag{8.13}$$

Combining (8.11) and (8.13) we then have for $z \in \mathbb{C} \setminus \Sigma_R$,

$$R(z) - I - \sum_{k=1}^{l} \frac{R_k(z)}{n^k} = \frac{1}{2\pi i} \int_{\Sigma_R} \left(R_-(s)\Delta(s) - \sum_{k=1}^{l} \sum_{j=1}^{k} \frac{R_{k-j,-}(s)\Delta_j(s)}{n^k} \right) \frac{ds}{s-z}.$$

One easily verifies that we can rewrite the term in the parenthesis as follows

$$R_-(s)\Delta(s) - \sum_{k=1}^{l}\sum_{j=1}^{k}\frac{R_{k-j,-}(s)\Delta_j(s)}{n^k} \;=\; (R_-(s)-I)\left(\Delta(s) - \sum_{k=1}^{l-1}\frac{\Delta_k(s)}{n^k}\right)$$

$$+\left(\Delta(s) - \sum_{k=1}^{l}\frac{\Delta_k(s)}{n^k}\right) + \sum_{k=1}^{l-1}\frac{\Delta_k(s)}{n^k}\left(R_-(s) - I - \sum_{j=1}^{l-k}\frac{R_{j,-}(s)}{n^j}\right). \tag{8.14}$$

From (8.2), (8.7), and the fact that each Δ_j is bounded on Σ_R, it follows that each term in (8.14) is $O\left(n^{-(l+1)}\right)$ as $n\to\infty$, uniformly for $s \in \Sigma_R$. Hence the norm of the left-hand side of (8.14) is $\leq \dfrac{c}{n^{l+1}}$ for some constant c uniformly for $s\in\Sigma_R$, and so

$$\left\| R(z) - I - \sum_{k=1}^{l}\frac{R_k(z)}{n^k}\right\| \leq \frac{c}{n^{l+1}}\frac{1}{2\pi}\int_{\Sigma_R}\frac{|ds|}{|s-z|}.$$

Since the contour Σ_R is bounded and $|s-z|$ is uniformly bounded away from 0 for $s\in\Sigma_R$ and $|z|\geq 2$, we obtain (8.10) for some constant C. This completes the proof of the lemma.

□

The functions R_k can be computed from the known form (8.2), (8.5) and (8.6) of the jump matrix. We will do the calculations explicitly for the first two functions $R_1(z)$ and $R_2(z)$. It will then be clear how to proceed for the further terms.

8.2.1 Determination of R_1

Expanding the jump relation $R_+ = R_-(I+\Delta)$ up to order $1/n$ we find, cf. (8.12)

$$R_{1,+}(s) - R_{1,-}(s) = \Delta_1(s), \qquad \text{for } s\in\partial U_\delta \cup \partial\tilde{U}_\delta. \tag{8.15}$$

Then (8.15) and (8.8)–(8.9) with $k=1$, give an additive RHP for R_1. This RHP can be solved by the Sokhotskii-Plemelj formulas, but in this case we can state the solution explicitly as follows. From Lemma 8.1 we know that $\Delta_1(z)$ is analytic in a neighborhood of $z=-1$ and $z=1$ except for simple poles at ±1. So

$$\Delta_1(z) = \frac{A^{(1)}}{z-1} + O(1), \quad \text{as } z\to 1, \qquad \Delta_1(z) = \frac{B^{(1)}}{z+1} + O(1), \quad \text{as } z\to -1,$$

for certain constant matrices $A^{(1)}$ and $B^{(1)}$. By inspection we then see that

$$R_1(z) = \begin{cases} \dfrac{A^{(1)}}{z-1} + \dfrac{B^{(1)}}{z+1}, & \text{for } z\in\mathbb{C}\setminus\left(\overline{U}_\delta\cup\overline{\tilde{U}}_\delta\right), \\[2ex] \dfrac{A^{(1)}}{z-1} + \dfrac{B^{(1)}}{z+1} - \Delta_1(z), & \text{for } z\in U_\delta\cup\tilde{U}_\delta. \end{cases} \tag{8.16}$$

solves the additive RHP (8.8), (8.9), (8.15).

The constant matrix $A^{(1)}$ can be calculated from the formula (8.5) with $k=1$, and the known behavior of g, N, and W near 1. The behavior of g is given by (6.14), and for N and W we have as in (6.37)

$$N(z)W(z)^{\sigma_3} = D_\infty^{\sigma_3}\begin{pmatrix} \frac{a(z)+a(z)^{-1}}{2} & \frac{a(z)-a(z)^{-1}}{2i} \\ \frac{a(z)-a(z)^{-1}}{-2i} & \frac{a(z)+a(z)^{-1}}{2}\end{pmatrix}\left(\frac{W(z)}{D(z)}\right)^{\sigma_3}, \tag{8.17}$$

where W/D has an expansion near 1 given in Lemma 6.4. The functions $a(z) = \frac{(z-1)^{1/4}}{(z+1)^{1/4}}$ and $\varphi(z) = z + (z^2-1)^{1/2}$ that appear in (8.17) and Lemma 6.4 also have expansions near 1. We then obtain

$$A^{(1)} = \frac{4\alpha^2-1}{16}\, D_\infty^{\sigma_3} \begin{pmatrix} -1 & i \\ i & 1 \end{pmatrix} D_\infty^{-\sigma_3}, \tag{8.18}$$

Similarly, $B^{(1)}$ follows from (8.6), Lemma 6.6, and the behavior of $\tilde{g}$, N, and $\tilde{W}$ near -1. The result is that

$$B^{(1)} = \frac{4\beta^2-1}{16}\, D_\infty^{\sigma_3} \begin{pmatrix} 1 & i \\ i & -1 \end{pmatrix} D_\infty^{-\sigma_3}. \tag{8.19}$$

This completes the determination of R_1.

Remark 8.4 To calculate $A^{(1)}$ we only need the leading terms in the expansions of g, N, and W. So in particular it is enough to use $W(z)/D(z) = 1 + O(|z-1|^{1/2})$ as $z \to 1$, see Lemma 6.4. Similarly, for $B^{(1)}$ it is enough to know $\tilde{W}(z)/D(z) = 1 + O(|z+1|^{1/2})$ as $z \to -1$, see Lemma 6.6. This means that the analytic factor h in the weight only plays a role through the constant D_∞ in the determination of R_1.

8.2.2 Determination of R_2

Expanding the jump relation $R_+ = R_-(I + \Delta_R)$ up to order $1/n^2$ we find, cf. (8.12),

$$R_{2,+}(s) - R_{2,-}(s) = R_{1,-}(s)\Delta_1(s) + \Delta_2(s), \qquad \text{for } s \in \partial U_\delta \cup \partial \tilde{U}_\delta. \tag{8.20}$$

We view (8.20) as a jump relation for R_2 on $\partial U_\delta \cup \partial \tilde{U}_\delta$ with additive jump matrix

$$R_{1,-}(s)\Delta_1(s) + \Delta_2(s).$$

Then (8.20) and (8.8)–(8.9) with $k = 2$, give an additive RHP for R_2.

Since $R_{1,-}(s)$ is the boundary value of the restriction of R_1 to the disks U_δ and $\tilde{U}_\delta$, and since Δ_1 and Δ_2 are analytic in a neighborhood of -1 and 1, except for simple poles at ± 1, see Lemma 8.2, we have

$$R_1(z)\Delta_1(z) + \Delta_2(z) = \frac{A^{(2)}}{z-1} + O(1), \qquad \text{as } z \to 1,$$

and

$$R_1(z)\Delta_1(z) + \Delta_2(z) = \frac{B^{(2)}}{z+1} + O(1), \qquad \text{as } z \to -1,$$

for certain constant matrices $A^{(2)}$ and $B^{(2)}$. As in the determination of R_1, we then find

$$R_2(z) = \begin{cases} \dfrac{A^{(2)}}{z-1} + \dfrac{B^{(2)}}{z+1}, & \text{for } z \in \mathbb{C} \setminus \left(\overline{U}_\delta \cup \overline{\tilde{U}}_\delta\right), \\ \dfrac{A^{(2)}}{z-1} + \dfrac{B^{(2)}}{z+1} - R_1(z)\Delta_1(z) - \Delta_2(z), & \text{for } z \in U_\delta \cup \tilde{U}_\delta. \end{cases} \tag{8.21}$$

The calculation of $A^{(2)}$ is somewhat more complicated than the determination of $A^{(1)}$. It involves the two term expansion of the functions g, W/D, a, and φ near $z = 1$. In particular we need two terms in the expansion in Lemma 6.4, which means that the constant c_0 comes in. Using Maple we are able to compute $A^{(2)}$, and the result is

$$A^{(2)} = \frac{4\alpha^2-1}{256} D_\infty^{\sigma_3} \begin{pmatrix} A_2(\alpha,\beta,c_0) & iB_2(\alpha,\beta,c_0) \\ iC_2(\alpha,\beta,c_0) & D_2(\alpha,\beta,c_0) \end{pmatrix} D_\infty^{-\sigma_3}, \tag{8.22}$$

with c_0 given by formula (1.11) and

$$\begin{aligned} A_2(\alpha,\beta,c_0) &= 8\alpha + 8\beta + 8c_0 - 4\beta^2 + 1, \\ D_2(\alpha,\beta,c_0) &= -8\alpha - 8\beta - 8c_0 - 4\beta^2 + 1, \\ B_2(\alpha,\beta,c_0) &= -8\alpha - 8\beta - 8c_0 + 4\alpha^2 + 4\beta^2 - 10, \\ C_2(\alpha,\beta,c_0) &= -8\alpha - 8\beta - 8c_0 - 4\alpha^2 - 4\beta^2 + 10. \end{aligned}$$

Similarly, the result for $B^{(2)}$ is

$$B^{(2)} = \frac{4\beta^2-1}{256} D_\infty^{\sigma_3} \begin{pmatrix} -A_2(\beta,\alpha,d_0) & iB_2(\beta,\alpha,d_0) \\ iC_2(\beta,\alpha,d_0) & -D_2(\beta,\alpha,d_0) \end{pmatrix} D_\infty^{-\sigma_3}, \tag{8.23}$$

with d_0 given by formula (1.12).

Remark 8.5 To calculate R_2 we need two terms in the expansion of W/D near 1 and $\tilde{W}/D$ near -1, cf. Lemmas 6.4 and 6.6. That's why we see the influence of the analytic factor h in the form of the coefficients c_0 and d_0.

8.2.3 Result for general R_k

In a similar (although increasingly more complicated) way we can determine R_k for every k. The calculations become unreasonable to do by hand. Assisted by the computer algebra package Maple, we find for R_3,

$$R_3(z) = \frac{A^{(3)}}{z-1} + \frac{B^{(3)}}{z+1} + \frac{C^{(3)}}{(z-1)^2} + \frac{D^{(3)}}{(z+1)^2}, \qquad \text{for } z \in \mathbb{C} \setminus \left(\overline{U}_\delta \cup \overline{\tilde{U}}_\delta\right). \tag{8.24}$$

where $A^{(3)}$ and $B^{(3)}$ are given by

$$A^{(3)} = \frac{4\alpha^2-1}{8192} D_\infty^{\sigma_3} \begin{pmatrix} A_3(\alpha,\beta,c_0,d_0) & iB_3(\alpha,\beta,c_0,d_0) \\ iC_3(\alpha,\beta,c_0,d_0) & D_3(\alpha,\beta,c_0,d_0) \end{pmatrix} D_\infty^{-\sigma_3},$$

$$B^{(3)} = \frac{4\beta^2-1}{8192} D_\infty^{\sigma_3} \begin{pmatrix} -A_3(\beta,\alpha,d_0,c_0) & iB_3(\beta,\alpha,d_0,c_0) \\ iC_3(\beta,\alpha,d_0,c_0) & -D_3(\beta,\alpha,d_0,c_0) \end{pmatrix} D_\infty^{-\sigma_3}$$

with c_0 and d_0 given by the formulas (1.11) and (1.12) respectively, and

$$\begin{aligned} A_3(\alpha,\beta,c_0,d_0) &= 16(4\beta^2-1)(c_0+d_0+2\alpha+2\beta) - 4\alpha^2(4\beta^2-1) \\ &\quad -128(\alpha^2+\beta^2+c_0^2) - 256c_0(\alpha+\beta) - 256\alpha\beta + 12\beta^2 - 16\beta^4 - 2, \\ D_3(\alpha,\beta,c_0,d_0) &= 16(4\beta^2-1)(c_0+d_0+2\alpha+2\beta) + 4\alpha^2(4\beta^2-1) \\ &\quad +128(\alpha^2+\beta^2+c_0^2) + 256c_0(\alpha+\beta) + 256\alpha\beta - 12\beta^2 + 16\beta^4 + 2, \end{aligned}$$

and

$$\begin{aligned}
B_3(\alpha,\beta,c_0,d_0) &= 384(\alpha+\beta)^2+384c_0(c_0+2\alpha+2\beta)-388\alpha^2-252\beta^2+64\alpha^4\\
&\quad +48\beta^4+144\alpha^2\beta^2+528-384(\alpha+\beta)(\alpha^2+\beta^2)+960(\alpha+\beta)\\
&\quad -192\beta^2(c_0+d_0)-384c_0\alpha^2+912c_0+48d_0,\\
C_3(\alpha,\beta,c_0,d_0) &= 384(\alpha+\beta)^2+384c_0(c_0+2\alpha+2\beta)-388\alpha^2-252\beta^2+64\alpha^4\\
&\quad +48\beta^4+144\alpha^2\beta^2+528+384(\alpha+\beta)(\alpha^2+\beta^2)-960(\alpha+\beta)\\
&\quad +192\beta^2(c_0+d_0)+384c_0\alpha^2-912c_0-48d_0.
\end{aligned}$$

For $C^{(3)}$ and $D^{(3)}$, we find

$$\begin{aligned}
C^{(3)} &= \frac{(4\alpha^2-1)(4\alpha^2-9)(4\alpha^2-25)}{12288}\begin{pmatrix}-1 & i\\ i & 1\end{pmatrix},\\
D^{(3)} &= \frac{(4\beta^2-1)(4\beta^2-9)(4\beta^2-25)}{12288}\begin{pmatrix}-1 & -i\\ -i & 1\end{pmatrix}.
\end{aligned}$$

For general k, we get that $R_k(z)$ in the region $\mathbb{C}\setminus\left(\overline{U_\delta}\cup\overline{\tilde{U}_\delta}\right)$ is a rational function with poles at 1 and -1. The residues in 1 and -1 are denoted by $A^{(k)}$ and $B^{(k)}$ respectively. Then

$$R_k(z)=\frac{A^{(k)}}{z-1}+\frac{B^{(k)}}{z+1}+O\left(\frac{1}{z^2}\right), \qquad \text{as } z\to\infty. \tag{8.25}$$

9 Proof of Theorems 1.4, 1.6, and 1.10

In this section we go back to the orthogonal polynomials and prove the Theorems 1.4, 1.6, and 1.10. By tracing back the steps

$$Y\mapsto T\mapsto S\mapsto R$$

and using the asymptotic expansion for R obtained in the previous section, we obtain an asymptotic expansion for Y. We will restrict ourselves to the asymptotics in the exterior region $\mathbb{C}\setminus[-1,1]$. The asymptotics on the interval $(-1,1)$ and near the endpoints will be considered in the next section. Let K be a closed set in $\overline{\mathbb{C}}\setminus[-1,1]$. Then we can choose the lens and the regions U_δ, $\tilde{U}_\delta$ disjoint from K. From (3.7), (4.2), and (7.1), we then obtain

$$Y(z)=2^{-n\sigma_3}R(z)N(z)\varphi(z)^{n\sigma_3}, \qquad \text{for } z\in K. \tag{9.1}$$

9.1 Asymptotics for π_n

We start with the proof of Theorem 1.4 concerning the asymptotics of the monic orthogonal polynomials $\pi_n(z)$ for $z\in K$.

Proof of Theorem 1.4. Since $\pi_n = Y_{11}$ we obtain from (9.1)

$$\pi_n(z) = 2^{-n}\varphi(z)^n \left(R_{11}(z)N_{11}(z) + R_{12}(z)N_{21}(z)\right). \tag{9.2}$$

If we use (5.5) and (8.7), we get uniformly for z in K,

$$\frac{2^n\pi_n(z)}{\varphi(z)^n} \sim \frac{D_\infty}{D(z)}\frac{a(z)+a(z)^{-1}}{2}\left[1+\sum_{k=1}^{\infty}\frac{(R_k)_{11}(z)}{n^k}\right] + \frac{1}{D_\infty D(z)}\frac{a(z)-a(z)^{-1}}{-2i}\left[\sum_{k=1}^{\infty}\frac{(R_k)_{12}(z)}{n^k}\right].$$

Since

$$\frac{a(z)+a(z)^{-1}}{2} = \frac{\varphi(z)^{1/2}}{\sqrt{2}(z^2-1)^{1/4}},$$

we obtain Theorem 1.4 with

$$\Pi_k(z) = (R_k)_{11}(z) + \frac{i}{D_\infty^2}\frac{a(z)-a(z)^{-1}}{a(z)+a(z)^{-1}}(R_k)_{12}(z). \tag{9.3}$$

Using (8.16), (8.18), and (8.19) and simplifying the expressions, we see that Π_1 is given by (1.13). From (8.21), (8.22), and (8.23), we obtain the formula (1.14) for Π_2. □

Note that the factor D_∞^{-2} in the formula (9.3) is cancelled by the factor D_∞^2 which is included in the $(1,2)$ entry of R_k (see formulas (8.16), (8.18), (8.19) for the case $k=1$), so that D_∞ does not appear in the final expression for Π_k. This is due to the fact that we are dealing with monic polynomials in Theorem 1.4. The functions $\Pi_k(z)$ are rational functions of $\varphi(z)$ with coefficients that are polynomial expressions in α, β, and the coefficients c_k and d_k.

9.2 Asymptotics for γ_n

We next consider the asymptotic behavior of the leading coefficient γ_n of the orthonormal polynomial.

Proof of Theorem 1.6. To emphasize the n-dependence, let us use $Y^{(n)}$ to denote the solution (2.5) of the RHP for Y. Then we see from (2.5) that

$$Y_{21}^{(n+1)}(z) = -2\pi i\gamma_n^2\pi_n(z).$$

Since π_n is a monic polynomial of degree n, we therefore have that

$$\gamma_n^2 = -\frac{1}{2\pi i}\lim_{z\to\infty} z^{-n}Y_{21}^{(n+1)}(z).$$

This expression appeared earlier in [12, Theorem 3.1] and [10, Section 3.2]. Using (9.1) (with n replaced by $n+1$) we find that for z in the exterior region,

$$\gamma_n^2 = -\frac{1}{2\pi i}\lim_{z\to\infty}\left[2^{n+1}\left(\frac{\varphi(z)}{z}\right)^{n+1}\left(zR_{21}^{(n+1)}(z)N_{11}(z) + zR_{22}^{(n+1)}(z)N_{21}(z)\right)\right], \tag{9.4}$$

where $R^{(n+1)}$ denotes the R matrix corresponding to $n+1$. Recall that N does not depend on n.

We note that

$$\frac{\varphi(z)}{z} = 2 + O\left(\frac{1}{z^2}\right), \qquad \text{as } z \to \infty, \tag{9.5}$$

and

$$N_{11}(z) = 1 + O\left(\frac{1}{z}\right), \qquad R_{22}^{(n+1)}(z) = 1 + O\left(\frac{1}{z}\right), \qquad \text{as } z \to \infty. \tag{9.6}$$

From (5.5) it follows that

$$N_{21}(z) = D_\infty^{-1} D(z)^{-1} \frac{a(z) - a(z)^{-1}}{-2i} = \frac{1}{2iD_\infty^2 z} + O\left(\frac{1}{z^2}\right), \quad \text{as } z \to \infty, \tag{9.7}$$

and from (8.7)

$$R_{21}^{(n+1)}(z) \sim \sum_{k=1}^{\infty} \frac{(R_k)_{21}(z)}{(n+1)^k}, \qquad \text{as } n \to \infty.$$

Using this and Lemma 8.3 and (8.25) we find

$$\lim_{z\to\infty} zR_{21}(z) \sim \sum_{k=1}^{\infty} \frac{A_{21}^{(k)} + B_{21}^{(k)}}{(n+1)^k}, \qquad \text{as } n \to \infty. \tag{9.8}$$

Combining (9.4)–(9.8), we obtain that γ_n^2 has an asymptotic expansion

$$\gamma_n^2 \sim \frac{2^{2n}}{\pi D_\infty^2} \left(1 + 2iD_\infty^2 \sum_{k=1}^{\infty} \frac{A_{21}^{(k)} + B_{21}^{(k)}}{(n+1)^k}\right), \qquad \text{as } n \to \infty.$$

Taking square roots, and rearranging terms we obtain the asymptotic expansion (1.15) for γ_n. Using the exact expressions for $A^{(1)}$, $B^{(1)}$, $A^{(2)}$, and $B^{(2)}$ given in (8.18), (8.19), (8.22), and (8.23), we obtain the explicit expressions (1.16) and (1.17) for Γ_1 and Γ_2. □

9.3 Asymptotics for the recurrence coefficients

Recall the three term recurrence relation

$$\pi_{n+1}(z) = (z - b_n)\pi_n(z) - a_n^2 \pi_{n-1}(z) \tag{9.1}$$

satisfied by the monic orthogonal polynomials. In this section we give the proof of Theorem 1.10 concerning the asymptotic behavior for the recurrence coefficients a_n and b_n.

Proof of Theorem 1.10. First, we determine formulas for a_n and b_n in terms of Y. We use an argument taken from [10, Section 3.3]. Let $Y^{(n)}$ and $Y^{(n+1)}$ be the solutions of the RHP for Y corresponding to n and $n+1$, respectively. Since $Y^{(n+1)}$ and $Y^{(n)}$ are analytic in $\mathbb{C} \setminus [-1,1]$ and satisfy the same jump relation on the interval $(-1,1)$, it follows that

$$H^{(n)} := Y^{(n+1)} \left(Y^{(n)}\right)^{-1} \tag{9.2}$$

is analytic in $\mathbb{C}\setminus\{-1,1\}$. In the same way as was done in the proof of Lemma 2.3, we can prove that $H^{(n)}$ has removable singularities at the points ± 1. Therefore $H^{(n)}$ is entire. From the asymptotic behavior (2.2), the definition (9.2), and the fact that $\det Y^{(n)} \equiv 1$, it follows that

$$H^{(n)}(z) = \begin{pmatrix} z + O(1) & O(1) \\ O(1) & O\left(z^{-1}\right) \end{pmatrix}, \qquad \text{as } z \to \infty.$$

Using Liouville's theorem we then find that

$$H^{(n)}(z) = \begin{pmatrix} z - r_n & s_n \\ t_n & 0 \end{pmatrix} \tag{9.3}$$

for certain constants r_n, s_n, and t_n. Thus

$$Y^{(n+1)}(z) = \begin{pmatrix} z - r_n & s_n \\ t_n & 0 \end{pmatrix} Y^{(n)}(z). \tag{9.4}$$

The $(1,1)$ entry of this matrix relation gives

$$\pi_{n+1}(z) = (z - r_n)\pi_n(z) - 2\pi i \gamma_{n-1}^2 s_n \pi_{n-1}(z),$$

which is the recurrence relation for the orthogonal polynomials. Comparing with (9.1), we see that $b_n = r_n$ and $a_n^2 = 2\pi i \gamma_{n-1}^2 s_n$, The $(2,1)$ entry of (9.4) shows that $-2\pi i \gamma_n^2 = t_n$. Thus

$$b_n = r_n, \qquad a_n^2 = -s_n t_{n-1}. \tag{9.5}$$

Using (9.2), (9.3), (9.5) and the fact that $\det Y^{(n)}(z) = 1$, we find that

$$b_n = z - Y_{11}^{(n+1)}(z) Y_{22}^{(n)}(z) + Y_{12}^{(n+1)}(z) Y_{21}^{(n)}(z),$$

and

$$a_n^2 = \left(Y_{11}^{(n+1)}(z) Y_{12}^{(n)}(z) - Y_{12}^{(n+1)}(z) Y_{11}^{(n)}(z)\right) \left(Y_{21}^{(n)}(z) Y_{22}^{(n-1)}(z) - Y_{22}^{(n)}(z) Y_{21}^{(n-1)}(z)\right),$$

for every $z \in \mathbb{C} \setminus [-1,1]$. From the asymptotic behavior (2.2) of Y we then find, upon letting $z \to \infty$,

$$b_n = \lim_{z\to\infty} \left(z - Y_{11}^{(n+1)}(z) Y_{22}^{(n)}(z)\right), \tag{9.6}$$

and

$$a_n^2 = \lim_{z\to\infty} z^2 Y_{12}^{(n)}(z) Y_{21}^{(n)}(z). \tag{9.7}$$

We use (9.6) and (9.7) to express the recurrence coefficients in terms of R. From (9.1) and (9.7), we get for the recurrence coefficient a_n

$$a_n^2 = \lim_{z\to\infty} z^2 \left(R_{21}^{(n)}(z) N_{11}(z) + R_{22}^{(n)}(z) N_{21}(z)\right) \left(R_{11}^{(n)}(z) N_{12}(z) + R_{12}^{(n)}(z) N_{22}(z)\right).$$

From the behavior of $R^{(n)}$ and N at infinity (in particular (5.5)) one then easily sees that

$$a_n^2 = \lim_{z\to\infty} \left(z R_{21}^{(n)}(z) + \frac{1}{2iD_\infty^2}\right) \left(-\frac{D_\infty^2}{2i} + z R_{12}^{(n)}(z)\right). \tag{9.8}$$

For b_n we find in the same way

$$b_n = \lim_{z\to\infty} \left(z - zR_{11}^{(n+1)}(z)R_{22}^{(n)}(z) \right). \tag{9.9}$$

In the asymptotic expansion for R, we may take the limit $z \to \infty$, by Lemma 8.3. We find

$$a_n^2 \sim \left(\frac{1}{2iD_\infty^2} + \sum_{k=1}^{\infty} \frac{A_{21}^{(k)} + B_{21}^{(k)}}{n^k} \right) \left(-\frac{D_\infty^2}{2i} + \sum_{k=1}^{\infty} \frac{A_{12}^{(k)} + B_{12}^{(k)}}{n^k} \right), \tag{9.10}$$

and

$$\begin{aligned} b_n &\sim \lim_{z\to\infty} \left[z - z \left(1 + \sum_{k=1}^{\infty} \frac{(R_k)_{11}(z)}{(n+1)^k} \right) \left(1 + \sum_{l=1}^{\infty} \frac{(R_l)_{22}(z)}{n^l} \right) \right] \\ &= \lim_{z\to\infty} -z \left(\sum_{k=1}^{\infty} \frac{(R_k)_{11}(z)}{(n+1)^k} + \sum_{l=1}^{\infty} \frac{(R_l)_{22}(z)}{n^l} \right) \\ &= -\sum_{k=1}^{\infty} \left(\frac{A_{11}^{(k)} + B_{11}^{(k)}}{(n+1)^k} + \frac{A_{22}^{(k)} + B_{22}^{(k)}}{n^k} \right). \end{aligned} \tag{9.11}$$

Expanding (9.10), we find a complete asymptotic expansion for a_n^2 in powers of $1/n$. The constant term is $1/4$, and the term with $1/n$ has coefficient

$$\frac{1}{2i} \left(D_\infty^{-2}(A_{12}^{(1)} + B_{12}^{(1)}) - D_\infty^2(A_{21}^{(1)} + B_{21}^{(1)}) \right),$$

which by the formulas (8.18) and (8.19) for $A^{(1)}$ and $B^{(1)}$ is equal to zero. Thus

$$a_n = \frac{1}{2} + O\left(\frac{1}{n^2}\right).$$

The full expansion of a_n follows from (9.10) and gives us the expansion (1.25) with explicitly computable coefficients A_k.

For b_n, we find from (9.11) that the $1/n$ term in the expansion has the coefficient

$$-\left(A_{11}^{(1)} + B_{11}^{(1)} + A_{22}^{(1)} + B_{22}^{(1)} \right),$$

which is zero by (8.18) and (8.19). Thus

$$b_n = O\left(\frac{1}{n^2}\right).$$

The full expansion (1.26) of b_n follows by rearranging terms in (9.11). □

Remark 9.1 Note that (9.7) can also be obtained directly from (2.5), since

$$Y_{21}(z) = -2\pi i\gamma_{n-1}^2 z^{n-1} \left(1 + O\left(\frac{1}{z}\right) \right)$$

and

$$Y_{12}(z) = \frac{1}{2\pi i} \int_{-1}^{1} \frac{\pi_n(x)w(x)}{x-z} dx = -\frac{1}{2\pi i} \gamma_n^{-2} z^{-n-1} \left(1 + O\left(\frac{1}{z}\right)\right).$$

Then (9.7) follows easily, because

$$a_n = \frac{\gamma_{n-1}}{\gamma_n}.$$

The formula (9.7) is due to Deift et al. [12, Theorem 3.1], see also [10, Section 3.2]. However the formula (9.6) is different from the one given in these references, which is due to the fact that the orthogonality weight is varying with n in [12].

10 Proof of Theorems 1.12 and 1.13

In this section we determine the asymptotics for the monic orthogonal polynomials π_n on the interval of orthogonality $[-1,1]$. We use the behavior of the first column of Y (which contains the orthogonal polynomials) on $[-1,1]$, which has already been determined, see [29]. In [29] this behavior has been used to derive universal behavior for eigenvalue correlations, associated to the modified Jacobi unitary ensemble, in the bulk and at the hard edge of the spectrum.

The behavior of the first column of Y in the bulk of the interval $[-1,1]$ is given by [29, Lemma 3.1]. Namely,

$$\begin{aligned} \begin{pmatrix} Y_{11}(x) \\ Y_{21}(x) \end{pmatrix} &= \frac{1}{\sqrt{w(x)}} 2^{-n\sigma_3} R(x) D_\infty^{\sigma_3} \\ &\times \begin{pmatrix} \frac{a_+(x)+a_+(x)^{-1}}{2} & \frac{a_+(x)-a_+(x)^{-1}}{2i} \\ \frac{a_+(x)-a_+(x)^{-1}}{-2i} & \frac{a_+(x)+a_+(x)^{-1}}{2} \end{pmatrix} e^{i(n\arccos x + \psi(x))\sigma_3} \begin{pmatrix} 1 \\ 1 \end{pmatrix}, \end{aligned} \tag{10.12}$$

for $x \in (-1+\delta, 1-\delta)$, where ψ is given by (1.34).

Proof of Theorem 1.12. Let K be a compact subset of $(-1,1)$. We can choose the radius δ of the disks U_δ and $\tilde{U}_\delta$ so small that $K \subset (-1+\delta, 1-\delta)$. From (10.12) and the facts that

$$\frac{a(z)+a(z)^{-1}}{2} = \frac{\varphi(z)^{1/2}}{\sqrt{2}(z^2-1)^{1/4}}, \quad \text{and} \quad \frac{a(z)-a(z)^{-1}}{2i} = i\frac{\varphi(z)^{-1/2}}{\sqrt{2}(z^2-1)^{1/4}}, \tag{10.13}$$

we obtain

$$\begin{aligned} \begin{pmatrix} Y_{11}(x) \\ Y_{21}(x) \end{pmatrix} &= \frac{1}{\sqrt{w(x)}} \frac{e^{-\frac{\pi i}{4}}}{\sqrt{2}(1-x^2)^{1/4}} 2^{-n\sigma_3} R(x) D_\infty^{\sigma_3} \\ &\times \begin{pmatrix} \varphi_+(x)^{1/2} & i\varphi_+(x)^{-1/2} \\ -i\varphi_+(x)^{-1/2} & \varphi_+(x)^{1/2} \end{pmatrix} e^{i(n\arccos x + \psi(x))\sigma_3} \begin{pmatrix} 1 \\ 1 \end{pmatrix}, \end{aligned}$$

for $x \in K$. Since $\varphi_+(x) = \exp(i \arccos x)$ we then find after an easy calculation

$$\begin{pmatrix} Y_{11}(x) \\ Y_{21}(x) \end{pmatrix} = \frac{1}{\sqrt{w(x)}} \frac{\sqrt{2}}{(1-x^2)^{1/4}} 2^{-n\sigma_3} R(x) D_\infty^{\sigma_3}$$

$$\times \begin{pmatrix} \cos\left((n+\frac{1}{2})\arccos x + \psi(x) - \frac{\pi}{4}\right) \\ -i\cos\left((n-\frac{1}{2})\arccos x + \psi(x) - \frac{\pi}{4}\right) \end{pmatrix}. \tag{10.14}$$

Since $Y_{11} = \pi_n$, and since $R_{11}(x) = 1 + O(1/n)$ and $R_{12}(x) = O(1/n)$ as $n \to \infty$ with error terms that hold uniformly for $x \in K$, and that have a full asymptotic expansion in powers of $1/n$, the theorem is then proven. □

Next, the behavior of the first column of Y near the endpoint 1 is given by [29, Lemma 3.3]. Namely,

$$\begin{pmatrix} Y_{11}(x) \\ Y_{21}(x) \end{pmatrix} = \sqrt{\frac{2\pi n}{w(x)}}\, 2^{-n\sigma_3} M_+(x) \begin{pmatrix} J_\alpha(n \arccos x) \\ \frac{i}{2}\arccos x J_\alpha'(n\arccos x) \end{pmatrix}, \tag{10.15}$$

for $x \in (1-\delta, 1)$, with $M(z)$ given by

$$M(z) = R(z)N(z)W(z)^{\sigma_3} \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & -i \\ -i & 1 \end{pmatrix} f(z)^{\sigma_3/4}. \tag{10.16}$$

Proof of Theorem 1.13. We need to determine a convenient expression for $M_+(x)$ and insert this into (10.15). From (5.5), (10.13) and (10.16) we have

$$M_+(x) = \frac{e^{-\frac{\pi i}{4}}}{2(1-x^2)^{1/4}} R(x) D_\infty^{\sigma_3} \begin{pmatrix} \varphi_+(x)^{1/2} & i\varphi_+(x)^{-1/2} \\ -i\varphi_+(x)^{-1/2} & \varphi_+(x)^{1/2} \end{pmatrix}$$

$$\times \left(\frac{W_+(x)}{D_+(x)}\right)^{\sigma_3} \begin{pmatrix} 1 & -i \\ -i & 1 \end{pmatrix} f_+(x)^{\sigma_3/4}. \tag{10.17}$$

It may be shown that $D_+(x) = \sqrt{w(x)}\exp(-i\psi(x))$, cf. [29, Remark 3.2]. We then have by (6.8)

$$\frac{W_+(x)}{D_+(x)} = e^{i(\psi(x) + \frac{\alpha\pi}{2})}.$$

Since $\varphi_+(x) = \exp(i\arccos x)$ we then obtain from (1.36) and (10.17)

$$\begin{aligned} M_+(x) &= \frac{e^{-\frac{\pi i}{4}}}{2(1-x^2)^{1/4}} R(x) D_\infty^{\sigma_3} \begin{pmatrix} e^{i\zeta_1(x)} & ie^{-i\zeta_1(x)} \\ -ie^{i\zeta_2(x)} & e^{-i\zeta_2(x)} \end{pmatrix} \begin{pmatrix} 1 & -i \\ -i & 1 \end{pmatrix} f_+(x)^{\sigma_3/4} \\ &= \frac{e^{-\frac{\pi i}{4}}}{(1-x^2)^{1/4}} R(x) D_\infty^{\sigma_3} \begin{pmatrix} \cos\zeta_1(x) & \sin\zeta_1(x) \\ -i\cos\zeta_2(x) & -i\sin\zeta_2(x) \end{pmatrix} f_+(x)^{\sigma_3/4}. \end{aligned} \tag{10.18}$$

Inserting the fact that

$$f_+(x)^{1/4} = \frac{e^{\pi i/4}}{\sqrt{2}} (\arccos x)^{1/2}$$

into (10.18) we find

$$M_+(x)\begin{pmatrix} J_\alpha(n\arccos x) \\ \frac{i}{2}\arccos x J'_\alpha(n\arccos x)\end{pmatrix}$$

$$= \frac{(\arccos x)^{1/2}}{\sqrt{2}(1-x^2)^{1/4}}R(x)D_\infty^{\sigma_3}\begin{pmatrix}\cos\zeta_1(x) & \sin\zeta_1(x) \\ -i\cos\zeta_2(x) & -i\sin\zeta_2(x)\end{pmatrix}\begin{pmatrix}J_\alpha(n\arccos x) \\ J'_\alpha(n\arccos x)\end{pmatrix}. \quad (10.19)$$

If we now insert (10.19) into (10.15), and use the facts that $Y_{11}=\pi_n$, $R_{11}(x)=1+O(1/n)$ and $R_{12}(x)=O(1/n)$ as $n\to\infty$, we obtain (1.35). Note that the error terms hold uniformly for $x\in(1-\delta,1)$ and have a full asymptotic expansion in powers of $1/n$. This proves the theorem. ☐
